1.0 SUMMARY

Project Location

The project lies in portions Section 32, Township 12 South, Range 64 West of the 6th Principal Meridian in El Paso County, Colorado. The site is located approximately two miles northeast of Falcon, Colorado.

Project Description

Total acreage involved in the project is approximately three hundred and seven acres. The proposed site development consists thirty-eight Rural Residential Lots, three hundred and sixty-two Urban Residential Lots, Commercial Lots, Industrial Lots and Open Space. The development will utilize municipal sewer and water on the Urban Residential, Commercial and Industrial Areas, and individual water wells and on-site wastewater treatment systems on the Rural Residential Lots. The existing house is to remain.

Scope of Report

This report presents the results of our geologic evaluation and treatment of engineering geologic hazard study.

Land Use and Engineering Geology

This site was found to be suitable for the proposed development. Areas were encountered where the geologic conditions will impose some constraints on development and land use. These include areas of shallow bedrock, expansive soils, artificial fill, erosion, floodplain, ponded water, shallow groundwater, seasonal shallow groundwater and potentially seasonally shallow groundwater areas. Based on the proposed development plan, it appears that these areas will have some impact on the development. These conditions will be discussed in greater detail in the report.

In general, it is our opinion that the development can be achieved if the observed geologic conditions on site are either avoided or properly mitigated. All recommendations are subject to the limitations discussed in the report.

2.0 GENERAL SITE CONDITIONS AND PROJECT DESCRIPTION

The site is located in portions Section 32, Township 12 South, Range 64 West of the 6th Principal Meridian in El Paso County, Colorado. The site is located approximately two miles northeast of Falcon, Colorado, north of Highway 24 and Judge Orr Road. The location of the site is as shown on the Vicinity Map, Figure 1.

The topography of the site is generally gradually to moderately sloping to the east-southeast. The drainages on site flow in a southerly direction through the eastern and western portions of the site. Several ponds are located in the western portion of the site along the mapped wetlands area. Water was observed in two ponds, and portions of the drainages in the eastern portion of the site at time of this investigation. Several seasonally wet and potentially seasonal wet areas are located in the eastern and western portions of the site. The site boundaries are indicated on the USGS Map, Figure 2. Previous land uses have included grazing and pasture land. The site contains primarily field grasses, weeds, cacti, and yuccas, with areas of scattered trees along the drainages and ponds. Site photographs, taken June 20, 2018, are included in Appendix A.

Total acreage involved in the proposed development is approximately three hundred and seven acres. Rural and Urban single-family residential lots are proposed along the northern and western portions of the site; Industrial areas are proposed in the east-central portion of the site; Commercial areas are proposed in the southern portion; and open space along the drainage area in the western portion of the site. The one-acre or smaller lots will be serviced municipal sewer and water, and the two and half-acre lots will have individual water wells and on-site wastewater treatment systems. The proposed Sketch Plan is presented in Figure 3.

3.0 SCOPE OF THE REPORT

The scope of the report will include the following:

A general geologic analysis utilizing published geologic data. Detailed site-specific
mapping will be conducted to obtain general information in respect to major geographic
and geologic features, geologic descriptions and their effects on the development of the
property.

4.0 FIELD INVESTIGATION

Our field investigation consisted of the preparation of a geologic map of any bedrock features and significant surficial deposits. The Natural Resource Conservation Service (NRCS), previously the Soil Conservation Service (SCS) survey was also reviewed to evaluate the site. The position of mappable units within the subject property are shown on the Geologic Map. Our mapping procedures involved both field reconnaissance and measurements and air photo reconnaissance and interpretation. The same mapping procedures have also been utilized to produce the Engineering Geology Map which identified pertinent geologic conditions affecting development. The field mapping was performed by personnel of Entech Engineering, Inc. on June 20, 2016.

Eight Test Borings were drilled on the site to determine general soil and bedrock characteristics. Two Test Pits were excavated in the area of the lots that will have individual on-site wastewater treatment systems. The locations of the test borings and test pits are indicated on the Development Plan/Test Boring Location Map, Figure 3. The Test Boring and Test Pit Logs are presented in Appendix B. Results of this testing will be discussed later in this report.

Laboratory testing was also performed on some of the soils to classify and determine the soils engineering characteristics. Laboratory tests included grain-size analysis ASTM D-422, Atterberg Limits ASTM D-4318, volume change testing using FHA Swell and Swell/Consolidation Tests. Sulfate testing was performed on select samples to evaluate potential for below grade concrete degradation due to sulfate attack. Results of the laboratory testing are included in Appendix C. A Summary of Laboratory Test Results is presented in Table 1.

5.0 SOIL, GEOLOGY AND ENGINEERING GEOLOGY

5.1 General Geology

Physiographically, the site lies in the western portion of the Great Plains Physiographic Province. Approximately seventeen miles to the west of the site is a major structural feature known as the Rampart Range Fault. This fault marks the boundary between the Great Plains

Physiographic Province and the Southern Rocky Mountain Province. The site exists within the southeastern edge of a large structural feature known as the Denver Basin. Bedrock in the area tends to be very gently dipping in a northwesterly direction (Reference 1). The rocks in the area of the site are sedimentary in nature and typically Upper Cretaceous in age. The bedrock underlying the site consists of the Dawson Formation. Overlying this formation are unconsolidated deposits of man-made fill soils, residual soils from in-situ weathering of the bedrock, and alluvial soils of Quaternary Age. The alluvial soils were deposited by water on site and as stream terraces along the drainages located on the site. Man-made soils exist as earthen dams located in the western portion of the site. The site's stratigraphy will be discussed in more detail in Section 5.3.

5.2 Soil Conservation Survey

The Natural Resource Conservation Service (Reference 2), previously the Soil Conservation Service (Reference 3) has mapped two soil types on the site (Figure 4). In general, the soils classify as gravelly sandy loam and sandy loam. The soils are described as follows:

Type	<u>Description</u>
19	Columbine gravelly sandy loam, 0 to 3% slopes
83	Stapleton sandy loam, 3 to 8% slopes

Complete descriptions of each soil type are presented in Appendix D. The soils have generally been described to have rapid to very rapid permeabilities. Possible hazards with soil erosion are present on the site. The erosion potential can be controlled with vegetation. The majority of the soils have been described to have slight to moderate erosion hazards.

5.3 Site Stratigraphy

The Falcon Quadrangle Geology Map showing the site is presented in Figure 5 (Reference 4). The Geology Map prepared for the site is presented in Figure 6. Five mappable units were identified on this site which are described as follows:

Qaf Artificial Fill of Holocene Age: These are recent deposits of man-made fill. They are associated with the man-made dams located in the western portion of the site.

These are located within a proposed open space area and will be avoided by future development. Additionally, erosion berms were observed in places on the property that have not been mapped on Figure 6.

Qa₁ Alluvium One of Late Holocene Age: These are water deposited sands, gravels and silts with minor clay lenses typically located along active stream channels and low stream-terrace deposits on the site. Alluvium One is correlative to the Post-Piney Creek Alluvium of the Denver area.

Qa₂ Alluvium Two of Early Holocene Age: These materials consist of water deposited alluvium, typically classified as a silty to well-graded sand, brown to dark brown in color and of moderate density. Alluvium Two is correlative to the Piney Creek Alluvium of the Denver area.

Qa₃ Alluvium Three of Late Pleistocene Age: These materials consist of lower stream terrace deposits, typically classified as silty to clayey gravelly sands. This deposit is usually highly stratified and may contain lenses of silt, clay, or cobbles. Alluvium Three is correlative to the Broadway Alluvium of the Denver area.

Tda Dawson Arkose of Paleocene to Eocene Age: The Dawson Arkose typically consists of arkosic sandstone with interbedded fine-grained sandstone, siltstone and claystone. Overlying this formation is a variable layer of residual soil. The residual soils were derived from the in-situ weathering of the bedrock materials on-site. These soils consisted of silty to clayey sands and sandy clays.

The soils listed above were mapped from site-specific mapping, the *Geologic Map of the Falcon Quadrangle* distributed by the Colorado Geological Survey in 2012 (Reference 4), the *Geologic Map of the Pueblo 1^o x 2^o Quadrangle*, distributed by the US Geological Survey in 1978 (Reference 5). The Test Borings and Test Pit were also used in evaluating the site and are included in Appendix B. The Geology Map prepared for the site is presented in Figure 6.

5.4 Soil Conditions

The soils encountered in the Test Borings can be grouped into four general soil types. The soils were classified using the Unified Soil Classification System (USCS).

<u>Soil Type 1</u>, classified as silty to slightly silty sand (SM, SM-SW), was encountered in all of the test borings at the existing ground surface and extending to depths ranging from one foot to 19 feet bgs. These soils were encountered at loose to dense states and at moist conditions. The majority of the soils were encountered and medium dense states. Samples tested had 8 to 32 percent of soil size particles passing the No. 200 Sieve. Atterberg Limits Testing resulted in the sand being non-plastic. Sulfate testing resulted in 0.01 percent sulfate by weight indicating the sand exhibits negligible potential for below grade concrete degradation.

<u>Soil Type 2</u>, classified as very clayey sand (SC), was encountered in Test Boring No. 2 at 14 feet and extended to 19 bgs. These soils were encountered at medium dense states and moist conditions. Samples tested had 47 percent of soil size particles passing the No. 200 Sieve. Atterberg Limits Testing resulted in a liquid limit of 30 and a plastic index of 14. FHA Swell testing resulted in expansion pressure of 940 psf, indicating a low to moderate expansion potential.

Soil Type 3, classified as silty to slightly silty sandstone and clayey sandstone (SM, SM-SW, SC), was encountered in six of the eight test borings at depths ranging from one foot to 19 feet bgs and extending to depths ranging from 16 feet to the termination of the test borings (20 feet). The sandstone was encountered at very dense states and at moist conditions. Samples tested had 7 to 42 percent of soil size particles passing the No. 200 Sieve. Atterberg Limits Testing on selected samples resulted a liquid limit of 37 and a plastic index of 15, and non-plastic results. Swell/Consolidation Testing resulted in the sandstone having a consolidation of 0.7 percent. Sulfate testing resulted in 0.00 to 0.01 percent sulfate by weight indicating the sandstone exhibits negligible potential for below grade concrete degradation.

<u>Soil Type 4</u>, classified as sandy to very sandy claystone (CL), was encountered in five of the test borings at depths ranging from 7 to 19 feet bgs and extending to the termination of the test borings (20 feet). The claystone was encountered at hard consistencies and at moist conditions. Samples tested had 53 to 87 percent of soil size particles passing the No. 200 Sieve.

Swell/Consolidation Testing resulted in an expansion of 1.3 percent, which indicates the claystone exhibits a low to moderate expansion potential. Atterberg Limits Testing resulted in a liquid limit of 30 and a plastic index of 11.

The Test Boring Logs are presented in Appendix B. Laboratory Test Results are presented in Appendix C. A Summary of Laboratory Test Results is presented in Table 1. The depth to bedrock is summarized in Table 2.

5.5 Groundwater

Groundwater was encountered in six of the test borings at depths ranging from 8.5 to 12 feet, groundwater was not encountered in the remaining borings which were drilled to 20 feet. Groundwater was encountered in Test Pit No. 2 at 5 feet. The depth to groundwater is summarized on Table 2. Areas of ponded water, seasonal shallow groundwater water, and potential seasonal shallow groundwater have been mapped along the drainages on-site. These areas are discussed in the following sections. Fluctuation in groundwater conditions may occur due to variations in rainfall and other factors not readily apparent at this time.

It should be noted that in the sandy materials on-site, some groundwater conditions might be encountered due to the variability in the soil profile. Isolated sand and gravel layers within the soils, sometimes only a few feet in thickness and width, can carry water in the subsurface. Groundwater may also flow on top of the underlying bedrock. Builders and planners should be cognizant of the potential for the occurrence of such subsurface water features during construction on-site and deal with each individual problem as necessary at the time of construction.

6.0 ENGINEERING GEOLOGY – IDENTIFICATION AND MITIGATION OF GEOLOGIC HAZARDS

As mentioned previously, detailed mapping has been performed on this site to produce an Engineering Geology Map Figure 6. This map shows the location of various geologic conditions of which the developers should be cognizant during the planning, design and construction

Entech Engineering, Inc.

stages of the project. These hazards and the recommended mitigation techniques are as follows:

Artificial Fill

These are recent man-made fill deposits associated with the dams located in the western portion of the site. This area is located in a proposed open space area and will be avoided by the development. One dam is in the area of a proposed roadway. It is anticipated that this dam will be removed and replaced with controlled fill during the site grading process. Areas of fill

other than these mapped may be encountered, particularly associated with erosion berms.

<u>Mitigation</u>: The earthen dams lie within defined drainages and should be avoided as building sites. The fill on this site is considered uncontrolled for construction purposes. It is anticipated the erosion berms would be mitigated during site grading or could be penetrated by foundations. Any uncontrolled fill encountered beneath foundations will require removal and recompaction at

a minimum of 95% of its maximum Modified Procter Dry Density, ASTM D-1557.

Collapsible Soils

The majority of the soils encountered on-site do not exhibit collapsible characteristics, however, areas of loose soils were encountered in the test borings drilled on site. Should loose or collapsible soils be encountered beneath foundations, recompaction and moisture conditioning of the upper 2 feet of soil at 95% of its maximum Modified Proctor Dry Density ASTM D-1557 will be required. Exterior flatwork and parking areas may also experience movement.

Proofrolling and recompaction of soft areas should be performed during site work.

Expansive Soils

Expansive soils were encountered in the test borings drilled on site. These occurrences are typically sporadic; therefore, none have been indicated on the maps. These clays and claystones, if encountered at foundation grade, can cause differential movement in structures.

These occurrences should be identified and dealt with on an individual basis.

<u>Mitigation</u> Should expansive soils be encountered beneath foundations, mitigation will be necessary. Mitigation of expansive soils will require special foundation design. Overexcavation and replacement with non-expansive soils at a minimum of 95% of its maximum Modified

Soil, Geology, Geologic Hazard, & Waste Water Study Meadowlake Ranch 13202 Judge Orr Road El Paso County, Colorado Job No. 180517 Proctor Dry Density, ASTM D-1557 is a suitable mitigation, which is common in the area. Floor slabs on expansive soils should be expected to experience movement. Overexcavation and replacement has been successful in minimizing slab movements. The use of structural floors should be considered for basement construction on highly expansive clays. Final recommendations should be determined after additional investigation of each building site.

Shallow Bedrock

Areas of shallow bedrock were encountered in some of the test borings drilled on site. Bedrock depths are summarized in Table 2. Areas of shallow bedrock may be encountered, particularly in areas mapped as Tda — Dawson Arkose Formation. Where shallow sandstone is encountered, higher allowable bearing capacities are anticipated. Shallow claystone may require mitigation of expansive soils. Overexcavation may be required in some areas to provide for soils of similar bearing capacity. The foundations should rest entirely on one soil type. Penetration to sandstone or overexcavation and replacement with compacted structural fill may be necessary in some areas. Excavation extending into the sandstone or claystone bedrock may be difficult and required track-mounted equipment or blasting.

Areas of Erosion

These are areas that are undergoing erosion by water and sheetwash producing minor gullies along some of the drainages on site.

<u>Mitigation</u>: Due to the nature of the soils on this site, virtually all the soils are subject to erosion by wind and water. Minor areas of erosion were observed on site, particularly in some of the drainages on site. Areas of erosion can occur across the entire site, particularly if the soils are disturbed during construction. Vegetation reduces the potential for erosion. Where erosion is actively taking place, check dams, regrading and revegetation using channel lining mats to anchor vegetation may be required. Further recommendations for erosion control are discussed under Section 9.0 "Erosion Control" of this report. Recommendations pertaining to revegetation may require input from a qualified landscape architect and/or the Natural Resource Conservation Service (previously Soil Conservation Service).

Groundwater and Floodplain Areas

Groundwater was encountered at depths ranging from 8.5 to 12 feet in six of the test borings drilled on site. Groundwater was encountered at 5 feet in Test Pit No. 2. Groundwater depths are summarized in Table 2. Areas within the drainages on-site have been identified as areas of seasonally wet and/or seasonally high groundwater areas. Water was observed in the ponds on-site and flowing in portions of the drainages in the eastern portion of the site. The site is not mapped within floodplain zones according to the FEMA Map No. 08041CO575F, Figure 7 (Reference 6), however, floodplain areas are mapped adjacent to the site. There are wetland areas identified by others along portions of the drainages in the eastern and western portions of the site. These areas are discussed as follows:

• Seasonal Shallow Groundwater Area

In these areas, we would anticipate periodic high subsurface moisture conditions and frost heave potential on a seasonal basis. Additional, highly organic soils could be encountered in these areas. The majority of these areas lie within defined drainages and it is anticipated they will be avoided by development. Some areas may be encountered on the site where perched water conditions exist where groundwater flows in permeable upper alluvial terrace materials on top of the impermeable bedrock. Any structures in or adjacent to these areas should follow the mitigation discussed below.

Mitigation: Foundations must have a minimum 30-inch depth for frost protection. In areas where high subsurface moisture conditions are anticipated periodically, subsurface perimeter drains are recommended to help prevent the intrusion of water into areas below grade. Typical drain details are presented in Figure 8. Any grading in these areas should be done to direct surface flow around construction to avoid areas of ponded water. Structures should not block drainages. All organic material should be completely removed prior to any fill placement. Unstable soil conditions should be expected in areas of shallow groundwater. Where excavations approach the groundwater level, stabilization utilizing shot rock or geogrids may be necessary. Underslab drains or capillary breaks and interceptor drains may be necessary to prevent the intrusion of groundwater into areas below grade. Typical drain details are presented in Figures 9 and 10. Finished floor levels must be located a minimum of one foot above floodplain levels. Specific floodplain locations and drainage studies are beyond the scope of this report.

Please call out if you anticipate the need for an under drain next to the sanitary sewer in the streets to collect the proposed foundation drains.

• Potentially Seasonal Shallow Groundwater Area

In these areas, we would anticipate the potential for periodically high subsurface moisture conditions, frost heave potential and highly organic soils. Many of these areas lie near or within defined drainages which can likely be avoided by the proposed development. In other areas, site grading may raise foundations above the groundwater level. The same mitigation recommendations for the seasonal shallow groundwater areas apply to the potentially seasonal shallow groundwater areas.

Areas of Ponded Water

These are areas of standing water behind earthen dams on site. These areas are designated as open space and we would not expect development in these areas. Either the dams can be avoided by construction or the areas may be completely regraded. Should complete regrading of the site be considered, all organic matter and soft, wet soils should be completely removed and stabilized before filling. Any drainage into these areas should be rerouted in a non-erosive manner off of the site where it does not create areas of ponded water around proposed structures. Structures adjacent to these areas may required drain systems, as mentioned above, to help prevent the intrusion of water into below grade areas.

6.1 Relevance of Geologic Conditions to Land Use Planning

As mentioned earlier in this report, we understand that the development will be Rural Residential, Urban Residential, Commercial and Industrial lots. It is our opinion that the existing geologic and engineering geologic conditions will impose some constraints on the proposed development and construction. The most significant problems affecting development will be those associated with the major drainages on site that are mitigated by avoidance. The minor drainages are being mitigated by site grading. Other hazards on site may be satisfactorily mitigated through proper engineering design and construction practices.

The upper materials are typically at loose to dense states. The medium dense to dense granular soils encountered in the upper soil profiles of the test borings should provide good support for foundations. Loose soils, if encountered at foundation depth, will require mitigation. Shallow bedrock may be encountered on portions of this site. Higher allowable bearing capacities for foundations can be expected in areas of shallow bedrock. Additionally,

overexcavation may be required to provide for soils of similar bearing capacity. Foundations anticipated for the site are standard spread footings possibly in conjunction with overexcavation in areas of expansive soils or loose soils or to provide similar bearing capacity in areas of shallow bedrock. Excavation is anticipated to be moderate with rubber-tired equipment for the site sand materials and will require track mounted equipment for the dense sandstone. Expansive layers may also be encountered in the soil and bedrock on this site. Areas of expansive soils encountered on site are sporadic; therefore, none have been indicated on the maps. Expansive soils, if encountered, will require special foundation design and/or overexcavation. These soils will not prohibit development.

Areas of seasonal and potentially seasonal high groundwater areas and ponded water were encountered on site. The majority of these areas are located in proposed open space areas and can be avoided by construction. Areas of perched groundwater conditions may be encountered where water flows through permeable sands on top of impermeable bedrock. Many areas will likely be filled during site grading, further raising foundations above the groundwater level. Any organic or soft soils should be removed prior to fill placement on the site. Unstable conditions should be expected where excavations approach the groundwater level. Stabilization using shot rock and geo grids may be necessary. Drains may be necessary for structures in or adjacent to these areas to help prevent the intrusion of water into areas below grade. Typical drain details are presented in Figures 8 through 10. Additional investigation is recommended as development plans are finalized. The water table may be at sufficient depths to minimize the effects on buildings, depending on site grading. The site does not lie within any floodplain zones according to the FEMA Map No. 08041CO575F, dated March 17, 1997 (Figure 7, Reference 6), however, floodplains are mapped adjacent to the site. Finished floor levels must be a minimum of one foot above the floodplain level. Exact locations of floodplain and specific drainage studies are beyond the scope of this report.

Areas of fill were observed on site associated with dams. The dams lie in designated open space and it is anticipated the dams will be avoided by development. An access way is proposed across one of the dams in the central western portion of the site. Proof rolling or recompaction may be required where roadways cross existing dams. Any uncontrolled fill encountered beneath foundations or roadways should be removed and recompacted at a minimum of 95% of its maximum Modified Proctor Dry Density, ASTM D-1557.

It is anticipated that foundations for the urban residential, rural residential, commercial and industrial areas will bear on medium dense sands or sandstone. Shallow spread footing foundations are anticipated. If expansive clay or claystone are encountered over excavation will be required.

In summary, development of the site can be achieved if the items mentioned above are mitigated. These items can be mitigated through proper design and construction or through avoidance. Additional investigations will be required as development plans are completed.

7.0 ECONOMIC MINERAL RESOURCES

Some of the sandy materials on-site could be considered a low-grade sand resource. According to the *El Paso County Aggregate Resource Evaluation Map* (Reference 7), the area is mapped with upland deposits. According to the *Atlas of Sand, Gravel and Quarry Aggregate Resources, Colorado Front Range Counties* distributed by the Colorado Geological Survey (Reference 8), areas of the site are mapped as A3: alluvial fan, sand resource and U4: Upland deposit, probable aggregate resource. According to the *Evaluation of Mineral and Mineral Fuel Potential* (Reference 9), the area of the site has been mapped as "Good" for industrial minerals. However, considering the silty nature of much of these materials and abundance of similar materials through the region and the close proximity to developed land, they would be considered to have little significance as an economic resource.

According to the Evaluation of Mineral and Mineral Fuel Potential of El Paso County State Mineral Lands (Reference 9), the site is mapped within the Denver Basin Coal Region. However, the area of the site has been mapped as "Poor" for coal resources. No active or inactive mines have been mapped in the area of the site. No metallic mineral resources have been mapped on-site (Reference 9).

The site has been mapped as "Fair" for oil and gas resources (Reference 9). No oil or gas fields have been discovered in the area of the site. The sedimentary rocks in the area may lack the geologic structure for trapping oil or gas; therefore, it may not be considered a significant resource. Hydraulic fracturing is a new method that is being used to extract oil and gas from

rocks. It utilizes pressurized fluid to extract oil and gas from rocks that would not normally be productive. The area of the site has not been explored to determine if the rocks underlying the site would be commercially viable utilizing hydraulic fracturing. The practice of hydraulic fracturing has come under review due to concerns about environmental impacts, health and safety.

8.0 ON-SITE WASTEWATER TREATMENT

The site was evaluated for on-site wastewater treatment systems for the proposed lots in accordance with El Paso Land Development Code. Two (2) tactile test pits were performed in the area of the proposed Rural Residential Lots. Test pits were located in anticipated areas of proposed on-site wastewater treatment systems (OWTS) for the development. The approximate locations of the test pits are indicated on Figure 3 and 6. The locations were chosen to determine a general understanding of the soil, bedrock and groundwater conditions across the site. The results of the test pits are presented in Table 2. There are several existing structures on the lot with existing septic systems. The records for the existing septic systems are included in Appendix E.

The Natural Resource Conservation Service (Reference 2), previously the Soil Conservation Service (Reference 3) has been mapped with two soil descriptions. The Soil Survey Map (Reference 2) is presented in Figure 4, and the Soil Survey Descriptions are presented in Appendix D. The soils are described as having rapid to very rapid percolation rates.

Soils encountered in the tactile test pits consisted of loamy sand to gravelly loamy sand overlying clayey to silty sandstone. The limiting layers encountered in the test pits are the clayey to silty sandstone, which corresponds to an LTAR values of 0.15 to 0.30 gallons per day per square foot. The bedrock was encountered at 2 to 5 feet in the test pits. The conditions encountered in the test pits will require designed systems. Groundwater was encountered at 5 feet in Test Pit No. 2. Absorption fields must be maintained a minimum of 4 feet above groundwater or bedrock. Groundwater was observed in Test Pit No. 2 at 5 feet.

In summary, it is our opinion the site is suitable for individual on-site wastewater treatment systems (OWTS) and that contamination of surface and subsurface water resources should not

occur provided the OWTS sites are evaluated and installed according to El Paso County Guidelines and properly maintained. Based on the testing performed as part of this investigation and the type of project, designed systems will likely be required for the majority of the lots. Designed systems are required in areas of shallow bedrock, shallow groundwater, or low infiltration rates. A Septic Suitability Map is presented in Figure 11. Areas where further investigation are indicated on the map to determine groundwater depths. Absorption fields must be located a minimum of 100 feet from any well, including those on adjacent properties. Absorption fields must also be located a minimum of 50 feet from any ponded areas and 25 feet from dry gulches. It should be noted that additional testing will be required for final submittal once lot layouts have been determined, and for the individual lots prior to construction.

9.0 EROSION CONTROL

The soil types observed on the site are mildly to highly susceptible to wind erosion, and moderately to highly susceptible to water erosion. A minor wind erosion and dust problem may be created for a short time during and immediately after construction. Should the problem be considered severe enough during this time, watering of the cut areas or the use of chemical palliative may be required to control dust. However, once construction has been completed and vegetation re-established, the potential for wind erosion should be considerably reduced.

With regard to water erosion, loosely compacted soils will be the most susceptible to water erosion, residually weathered soils become increasingly less susceptible to water erosion. For the typical soils observed on-site, allowable velocities or unvegetated and unlined earth channels would be on the order of 3 to 4 feet/second, depending upon the sediment load carried by the water. Permissible velocities may be increased through the use of vegetation to something on the order of 4 to 7 feet/second, depending upon the type of vegetation established. Should the anticipated velocities exceed these values, some form of channel lining material may be required to reduce erosion potential. These might consist of some of the synthetic channel lining materials on the market or conventional riprap. In cases where ditchlining materials are still insufficient to control erosion, small check dams or sediment traps may be required. The check dams will serve to reduce flow velocities, as well as provide small traps for containing sediment. The determination of the amount, location and placement of ditch linings, check dams and of the special erosion control features should be performed by or in

Entech Engineering, Inc.

conjunction with the drainage engineer who is more familiar with the flow quantities and

velocities.

Cut and fill slope areas will be subjected primarily to sheetwash and rill erosion. Unchecked rill

erosion can eventually lead to concentrated flows of water and gully erosion. The best means

to combat this type of erosion is, where possible, the adequate re-vegetation of cut and fill

slopes. Cut and fill slopes having gradients more than three (3) horizontal to one (1) vertical

become increasingly more difficult to revegetate successfully. Therefore, recommendations

pertaining to the vegetation of the cut and fill slopes may require input from a qualified

landscape architect and/or the Soil Conservation Service.

10.0 CLOSURE

It is our opinion that the existing geologic engineering and geologic conditions will impose some

constraints on development and construction of the site. The majority of these conditions can

be mitigated through proper engineering design and construction practices or avoidance. The

proposed development and use is consistent with anticipated geologic and engineering geologic

conditions.

It should be pointed out that because of the nature of data obtained by random sampling of such

variable and non-homogeneous materials as soil and rock, it is important that we be informed of

any differences observed between surface and subsurface conditions encountered in

construction and those assumed in the body of this report. Individual investigations for building

sites will be required prior to construction. Construction and design personnel should be made

familiar with the contents of this report. Reporting such discrepancies to Entech Engineering,

Inc. soon after they are discovered would be greatly appreciated and could possibly help avoid

construction and development problems.

This report has been prepared for Dan Ferguson, for application to the proposed project in

accordance with generally accepted geologic soil and engineering practices. No other warranty

expressed or implied is made.

NOTES:

- -GRAVEL SIZE IS RELATED TO DIAMETER OF PIPE PERFORATIONS-85% GRAVEL GREATER THAN 2x PERFORATION DIAMETER.
- -PIPE DIAMETER DEPENDS UPON EXPECTED SEEPAGE. 4-INCH DIAMETER IS MOST OFTEN USED.
- -ALL PIPE SHALL BE PERFORATED PLASTIC. THE DISCHARGE PORTION OF THE PIPE SHOULD BE NON-PERFORATED PIPE.
- -FLEXIBLE PIPE MAY BE USED UP TO 8 FEET IN DEPTH, IF SUCH PIPE IS DESIGNED TO WITHSTAND THE PRESSURES. RIGID PLASTIC PIPE WOULD OTHERWISE BE REQUIRED.
- -MINIMUM GRADE FOR DRAIN PIPE TO BE 1% OR 3 INCHES OF FALL IN 25 FEET.
- -DRAIN TO BE PROVIDED WITH A FREE GRAVITY OUTFALL, IF POSSIBLE. A SUMP AND PUMP MAY BE USED IF GRAVITY OUT FALL IS NOT AVAILABLE.

HENRY W. DANLEY P.E.

a. Site Preparation

Good construction techniques are essential if the mound is to function properly. The following techniques should be considered:

- Step 1: Rope off the site to prevent damage to the area during other construction activity on the lot. Vehicular traffic over the area should be prohibited to avoid soil compaction.
- Step 2: Stake out the mound perimeter and bed in the proper orientation. Reference stakes set some distance from the mound perimeter are also required in case the corner stakes are disturbed.
- Step 3: Cut and remove any excessive vegetation. Trees should be cut at ground surface and the stumps left in place.
- Step 4: Measure the average ground elevation along the upslope edge of the bed to determine the bottom elevation of the bed.

Step 6: Plow the area within the mound perimeter. Use a two bottom or larger moldboard plow, plowing 7 to 8 in. (18 to 20 cm) deep parallel to the contour. Single bottom plows should not be used, as the trace wheel runs in every furrow, compacting the soil. Each furrow should be thrown upslope. A chisel plow may be used in place of a moldboard plow. Roughening the surface with backhoe teeth may be satisfactory, especially in wooded sites with stumps. Rototilling is not recommended because of the damage it does to the soil structure. However, rototilling may be used in granular soils, such as sands.

Plowing should not be done when the soil is too wet. Smearing and compaction of the soil will occur. If a sample of the soil taken from the plow depth forms a wire when rolled between the palms, the soil is too wet. If it crumbles, plowing may proceed.

b. Fill Placement

Step 1: Place the fill material on the upslope edges of the plowed area. Keep trucks off the plowed area. Minimize traffic on the downslope side.

Step 2: Move the fill material into place using a small track type tractor with a blade. Always keep a minimum of 6 in. of material beneath the tracks of the tractor to minimize compaction of the natural soil. The fill material should be worked in this manner until the height of the fill reaches the elevation of the top of the absorption bed.

Step 3: With the blade of the tractor, form the absorption bed. Hand level the bottom of the bed, checking it for the proper elevation. Shape the sides to the desired slope.

c. Distribution Network Placement

- Step 1: Carefully place the coarse aggregate in the bed. Do not create ruts in the bottom of the bed. Level the aggregate to a minimum depth of 6 in. (15 cm).
- Step 2: Assemble the distribution network on the aggregate. The manifold should be placed so it will drain between doses, either out the laterals or back into the pump chamber. The laterals should be laid level.
- Step 3: Place additional aggregate to a depth of at least 2 in. (5 cm) over the crown of the pipe.
- Step 4: Place a suitable backfill barrier over the aggregate.

d. Covering

- Step 1: Place a finer textured soil material such as clay or silt loam over the top of the bed to a minimum depth of 6 in. (15 cm).
- Step 2: Place 6 in. (15 cm) of good quality topsoil over the entire mound surface.
- Step 3: Plant grass over the entire mound using grasses adapted to the area. Shrubs can be planted around the base and up the side-slopes. Shrubs should be somewhat moisture tolerant since the downslope perimeter may become moist during early spring and late fall. Plantings on top of the mound should be drought

tolerant, as the upper portion of the mound can become dry during the summer.

7.2.4.5 Operation and Maintenance

a. Routine Maintenance

A properly designed and constructed mound should operate satisfactorily with virtually no regular maintenance.

501 NORTH FOOTE AVENUE • COLORADO SPRINGS, CO 80909-4598 • (719) 578-3199 • FAX (719) 578-3214

CERTIFIED LETTER P 668 735 746

Martha McKinley 3204 Leslie Drive Colorado Springs, CO 80909

REFERENCE: Individual Sewage Disposal System failure

Location: 13202 Judge Orr Road, El Paso County, Colorado

Dear Ms McKinley:

On February 6, 1992 an inspection was conducted on the above referenced property by Michele Hanley, El Paso County Department of Health and Environment. Sewage was observed surfacing on the ground in the absorption area.

Discharge of sewage on the ground is in violation of 25-10-105, 106, and III, A, of the El Paso County Department of Health and Environment Individual Sewage Disposal System Regulations of 1990. Section III, A states in part:

"The owner of any structure where people live, work or congregate shall provide an adequate sewage disposal system in good working order and constructed, installed, and maintained in accordance with these regulations. Under no condition shall sewage contaminated material, sewage or effluent be permitted to be discharged upon the surface of the ground, or into the waters of the state..."

You shall have two (2) business days after receiving this letter to return the enclosed application for a repair permit, and thirty (30) days to obtain a permit to repair the system. You are requested to keep the system pumped as often as necessary to prevent the discharge of sewage on the ground surface until the system is repaired or replaced.

Please contact me if you have any questions regarding this matter.

Sincerely.

CERTIFIED LETTER P 767 702 527

Marta D. McKinley 13202 Judge Orr Road Peyton, Colorado 80831

REFERENCE: Individual Sewage Disposal System located at 13202 Judge Orr Road, Section 33, Township 12 South, Range 64 W of the 6th PM in El Paso County, Colorado

On June 12, 1992 an inspection of the sewage system on the above referenced property was conducted. Construction of the system was completed and the system covered prior to my arrival.

As a result the engineer designed sewage disposal system is not approved. For the sewage system to be approved, a letter is required from Henry W. Danley, PE, indicating the system was installed per his guidelines, and the design was inspected and approved by his office.

Please contact me if you have any questions regarding this matter.

Sincerely,

Donald A. Mydlowski

DIRECTIONS TO PROPERTY FROM MAIN HIGHWAYS:

PROPERTY IS TOCATED AT THE NORTH FAST INTERSECTION OF JUDGE ORR IRD AND HIGHWAY 24

NOTE— THIS PROPOSAL IS TO EXPAND/REPLACE THE CURRENT
SEPTIC FIELD. A SUPARATE PROPOSAL TO ESTABLISH A

NEW SUPTIC SYSTEM (TANK AND FIELD) FOR THE HOUSE

HAS BEEN SUBMITTED. THE CURRENT SYSTEM (AS REMIODELED)

WILL SERVE THE BIRAIER ONLY.

AN EXPANDED FIELD IS REQUIRED TO BY PASS AUGMENT THE CURRENT FIELD, WHICH IS EXHALDTED FROM OVER USE (THE CURRENT SEPTIL SYSTEM SERVES BOTH THE HOUSE AND TRAILER, AND IS IN ADEQUATE).

EL PASO COUNTY DEPARTMENT OF HEALTH AND ENVIRONMENT INDIVIDUAL SEWAGE DISPOSAL SYSTEM INSPECTION REPORT ±±4200000264

APPROVED: YES

ENVIRONMENTALIST

Permit Number: 10019
Date: April 4, 1996

Address: 13202 Judge Orr Road

Owner: Dan Ferguson

Legal Description: (See Application)

Residential system approved for five bedrooms.

System Installer: R. Palmer (R&R Ditching)

SEPTIC TANK

Commercially made tank constructed of precast concrete.

Capacity: 2250 gallons.

DISPOSAL FIELD

Chamber system utilizing Infiltratror brand leaching chambers in a bed (mound) configuration.

number of chambers: 64; sq. ft. per chamber: 18; reduction allowed: 0%;

sq.ft. required: 1152; total sq.ft. installed: 1152.

See engineers design for more details.

SYSTEM DESIGN

By Engineer: Yes:

Name of Design Engineer: John E. Wendt, PE. Approval Letter Provided: (Ye

WATER SUPPLY

Private Water Supply.

Proposed well is ≥ 50 ft.* from tank, and ≥100 ft.* from leach field.

*Approval shall be revoked if in the future these minimum horizontal distances are not maintained.

NOTES:

Per D. Mydlowski, design engineer to inspect for final cover, side slopes, and alarm installation. Except as noted below, all pipe in 4 inch diameter PVC SDR-35.

Re: Individual Sewage Disposal System (ISDS) for a 5 Bedroom House at 13202 Judge Orr Road, Colorado Springs, Co. 80831.

PRECOLATION TEST BY:

R & R Ditching, Inc. November 8, 1995

ABSORPTION RATE:

120 Minutes/Inch

SOIL CONTENT:

Clay

WATER SUPPLY:

Well

HOUSE SIZE:

5 Bedroom

AREAS OF SPECIAL CONCERN:

Impervious surface at

ground level.

SEPTIC TANK:

Provide: One 2,000 Gallon-- 2 Compartment Tank

WASTEWATER_FLOW

5 Bedrooms @ 150 GPD/ BR = 750 GPD

THEREFORE: Design flow shall be base upon: 1,125 GPD

OPTION I

Based upon no percable soil, a mound system may be developed.

A mound bed consisting of a sand/sandy loam mixture will infiltrate 1.0 gallons pr day/square foot. Therefore:

Net bed area of 24' x 48' shall be provided (Use 1,152 S.F).

Gross (basal) dimensions for this mound system shall be: 60' wide by 84' long- (based upon a bed area of 4' deep plus 12" of rockless chambers plus 12" of cover: Total: 6' high; sloping sides at 3:1 slope.

 Determine house, septic tank and bed locations. Note: This system shall be developed per El Paso County setback requirements for all elements of the system,

- 2. Level total (basal) area, remove any trees and other vegetation. For this system, trees should be cut to ground level and stumps left in place. Protect site from any vehicular traffic.
- 3. Stake out mound bed and gross perimeter. Possible reference stakes may be necessary some distance from site in case corner stakes are disturbed.
- 4. Determine elevation and location of the delivery pipe from lift station. This should be below frost line or sloped back to lift station so it may drain after dosing.
- 5. Scarify area within the net mound bed area (24' x 48') approximately 6' to 8" deep. This can be roughened with backhoe teeth.
- 6. Place fill material (sand/sandy loam) on bed area using a small track type tractor (with blade). Keep a minimum of 6" of soil beneath tracks to minimize compaction. Fill bed area to a height of 4' and level.
- 7. Lay 8 rockless chamber sections side by side (24') and add 8 chambers to each section (48' long). Cap front and rear. Run distribution pipes to each row of units from a distribution box at the entrance to system and manifold at rear (looped for best distribution). Determine location (and elevation) for an 8 outlet (9 hole) distribution box from the lift station. (again assure return drainage). NOTE: Use a "Tuf-Tite" 9HD2-or equal-distribution box with speed levelers to provide equal flow to each row. Drill a 3/8" hole in top of inlet elbow from lift station top prevent any vacuum effect.
- 8. Fill side wall area around perimeter and between rows of chambers to top of slots and walk into place. (bank run sand and gravel may be use for this fill).
- 9. Complete backfill of mound and entire basal area to an approximate 12' to 18" cover. *DO NOT USE WHEELED VEHICLES OF THE BED DURING CONSTRUCTION.
- 10. Upon completion seed with a mixture of Clover and dry land seed such as El Paso mix to prevent any erosion. Plant perimeter with water seeking shrubs such as ceders and Lilacs.

OPTION II

EVAPOTRANSPIRATION BED

Full and adequate evapotran Spiration (allowing for approximately 250% increase over area "lake evaporation" rate) because of location and plant growth, can be accomplished in a bed of approximately 3,600 SF (60' x 60'--80' x 45' etc.). This type and size of bed must be actively aerobic, well ventilated, well planted and well crowned.

Determine area sizing, level and stake. Remove all vegetation.

Undercut approximately 12" to 18" to form bed. Square up side around perimeter to form bed size.

Lay a 6" layer of $\frac{1}{4}$ " to 3/4" gravel on entire bottom of bed and level. In process of laying gravel, place 2" drilled piping ($\frac{1}{4}$ " drilled holes) approximately every 5' at the 2" level above bottom and 12" level as fill proceeds, vented to surface at both ends. Place a rain cap on vented piping.

Upon gravel place 4" perforated soil and drain piping-holes to gravel- at every 5' to 6' in bed. Manifold entrance and ends together to create a looped system.

Now cover entire bed with washed sand to a 3" crown above original leveled ground surface.

Immediately plant bed with broad-leafed plants and swamp type vegetation. Add evergreens, such as cedar bushes etc. to continue evapotranspiration during winter months.

A well crowned bed, surrounded by storm water drainage swales will provide run-off from system.

System will allow for approximately 20 to 25 days reservoir storage for winter and/or non active working bed times.

LIFT STATION

Provide a lift station downstream from the septic tank.

Lift station shall be capable of evacuating to either system (mound or evapotranspiration) approximately 200 to 300 gallons per pumping cycle and have reserve storage capability of approximately 100 gallons. A high water alarm system shall be installed to alert occupant of any pump failure or other malfunction. The discharge from the station shall be so sloped that upon completion of a dosing cycle wastewater in the pipe shall drain back to chamber. The station tank shall be water tight so no ground water can infiltrate into it. A riser from the access port shall extend a minimum of 6" above ground level to keep surface water from entering chamber

INSTRUCTIONS FOR ISDS USE

One must be aware of and assume responsibility for a continued inspection and maintenance of this entire septic system. Septic tank must be inspected and, if required, pumped on a regular basis (possibly every 18 to 24 months). Non-biodegradable products such as coffee grounds, cigarette butts, hygene products, diapers, plastic products of all kinds etc. shall not be run into system.

Water must be continuously monitored to assure that toilets and sinks are not allowed to run due to inattention or due to faulty or malfunctoning seals.

This design is in no way written guarantee the system will give indefinite trouble free service. Even with proper installation and maintenance, there remain many uncertainties and difficulties can still arise in the operation of the system in the future. Proper maintenance can assist in minimizing uncertainties, but cannot entirely eliminate them.

RESPECTFULLY SUBMINTED

JOHN E. WENDT P. E.
