## DRAINAGE STATEMENT

### Engineer's Statement:

The attached drainage plan and report were prepared under my direction and supervision and are correct to the best of my knowledge and belief. Said drainage report has been prepared according to the criteria established by the City/County for drainage reports and said report is in conformity with the master plan of the drainage basin. I accept responsibility for any liability caused by any negligent acts, errors or omissions on my part in preparing this report.

 3/28/08  
John P. Schwab, P.E. #29891

### Developer's Statement:

I, the developer have read and will comply with all of the requirements specified in this drainage report and plan.

Conditions:

FLOODPLAIN STATEMENT

To the best of my knowledge and belief, Falcon Acres Subdivision is not located in a FEMA designated floodplain, as shown on FIRM panel No. 08041C0800F, dated March 17, 1997.

John P. Schwab, P.E. #29891

3/28/08

## **I. GENERAL LOCATION AND DESCRIPTION**

### **A. Background**

Falcon Acres is a proposed residential subdivision located in northeastern El Paso County, Colorado. The Falcon Acres parcel (El Paso County Assessor's Number 44040-00-014) is located at the southwest corner of Curtis Road and Davis Road, as shown in Figure A1 (Appendix A). Falcon Acres Subdivision will consist of 8 rural residential lots (5-acre lot sizes) on a 47.6-acre parcel.

### **B. Scope**

This report is intended to fulfill the El Paso County requirements for a "Final Drainage Report" in support of the final subdivision plat approval process. This report will provide a summary of site drainage issues impacting the proposed residential development. The report will analyze impacts from upstream drainage patterns, site-specific developed drainage patterns, and impacts on downstream facilities. This report is based on the guidelines and criteria presented in the El Paso County Drainage Criteria Manual.

### **C. Site Location and Description**

The Falcon Acres parcel is located in the northeast quarter of the northeast quarter (NE1/4), and the east half of the east half of the northwest quarter of the northeast quarter (NE1/4) of Section 4, Township 14 South, Range 64 West of the 6th Principal Meridian. The site is currently inhabited by an existing ranch and pasture/meadow areas. The parcel is zoned RR-3 (rural residential), allowing for 5-acre minimum lot sizes. A new public road (Peaceful Prairie Road) extending south from Davis Road will provide access to the subdivision. Associated site improvements will include grading, driveway paving, and utility service improvements for the eight residential lots.

The parcel is bordered by existing rural residential lots on all sides, typically consisting of 5-acre lots. Davis Road borders the north boundary of the parcel, and Curtis Road borders the east boundary of the parcel. Ground elevations within the site range from approximately 6,530 to 6,550 feet above mean sea level.

The site is located near the upstream end of the Livestock Company Drainage Basin, which is tributary to the West Fork of Black Squirrel Creek. The terrain is gently rolling with average grades ranging from 1 to 5 percent. The existing site is a rural ranch parcel and pasture / meadow area.

## **D. General Soil Conditions**

According to the Soil Survey of El Paso County prepared by the Soil Conservation Service (SCS), on-site soils are comprised of Type 97, "Truckton sandy loam" (see Appendix B). These soils are classified as hydrologic soils group "B," with moderately rapid permeability, slow to medium surface runoff characteristics, and moderate hazard of erosion.

## **II. DRAINAGE BASINS AND SUB-BASINS**

### **A. Major Basin Description**

The proposed development lies completely within the Livestock Company Drainage Basin (CHWS 0400) as classified by El Paso County. Drainage from this site parcel flows southeasterly to a downstream confluence with the West Fork of Black Squirrel Creek.

### **B. Floodplain Impacts**

The project site is located beyond the limits of any 100-year floodplain delineated by the Federal Emergency Management Agency (FEMA). The floodplain limits in the vicinity of the site are shown in Flood Insurance Rate Map (FIRM) Number 08041C0800-F, dated March 17, 1997, as shown in Figure A2 (Appendix A).

### **C. Sub-Basin Description**

The existing drainage basins lying in and around the proposed development are depicted in Figure EX1 (Appendix A). The site is impacted by off-site drainage basins to the west, northwest, and southwest, which generally drain in an easterly direction across the site. Two existing sub-basins have been delineated within the site, each characterized by an existing depression as indicated by the hatched areas on Figure EX2 (Appendix A). Overflows from the existing depressions within the site would tend to drain northeasterly towards the intersection of Davis Road and Curtis Road, where no culvert currently exists. The natural drainage patterns within the site will be impacted through development by site grading and concentration of runoff in subdivision streets. Developed runoff will generally continue to follow historic paths.

## **III. DRAINAGE DESIGN CRITERIA**

### **A. Development Criteria Reference**

No Drainage Basin Planning Study (DBPS) has been completed for the Livestock Company Drainage Basin. No Master Development Drainage Plans (MDDP) were found for any adjacent subdivisions.

### **B. Hydrologic Criteria**

SCS procedures were utilized for analysis of the major off-site basin flows impacting the site. In accordance with El Paso County drainage criteria, SCS hydrologic calculations were based on the following assumptions:

- |   |   |
|---|---|
| • Design storm (minor)                      | 5-year                                    |
| • Design storm (major)                      | 100-year                                  |
| • Storm distribution                        | SCS Type IIA (eastern Colorado)           |
| • 100-year, 24-hour rainfall                | 4.4 inches per hour (NOAA isopluvial map) |
| • 5-year, 24-hour rainfall                  | 2.6 inches per hour (NOAA isopluvial map) |
| • Hydrologic soil type                      | B   |
| • SCS curve number - undeveloped conditions | 61 (pasture / range)                      |
| • SCS curve number - undeveloped conditions | 50 (range with upstream retention ponds)  |
| • SCS curve number - developed conditions   | 98 (paved areas)                          |
| • SCS curve number - developed 5-acre lots  | 63 (composite calculation)                |

A curve number of 50 has been selected for hydrologic modeling of upstream areas with existing retention ponds. This approach is consistent with the approved Final Drainage Report for Davis Ranch Subdivision, which is located a few miles east of this site.

Rational Method procedures were utilized for calculation of peak flows within the on-site drainage basins. Rational Method hydrologic calculations were based on the following assumptions:

• Design storm (minor)	5-year	
• Design storm (major)	100-year	
• Time of Concentration – Overland Flow	“Airport” equation (300’ max. developed)	
• Time of Concentration – Gutter/Ditch Flow	“SCS Upland” equation	
• Rainfall Intensities	El Paso County I-D-F Curve	
• Hydrologic soil type	B	
	<u>C5</u>	<u>C100</u>
• Runoff Coefficients - undeveloped:		
Existing pasture/range areas	0.25	0.35
• Runoff Coefficients - developed:		
Proposed lot areas (5-acre lots)	0.29	0.38 (composite calculation)

Hydrologic calculations are enclosed in Appendix B, and peak design flows are identified on the drainage basin drawings.

#### **IV. DRAINAGE FACILITY DESIGN**

##### **A. General Concept**

Development of the proposed subdivision will require site grading and paving work within 8 proposed rural residential lots, resulting in a limited amount of additional impervious area within the site. The general concept for management of developed storm runoff is to grade the home sites to provide positive drainage away from the building pads, and divert runoff to the proposed roadside ditches and existing grass-lined swales running through the property.

##### **B. Specific Details**

###### **1. Existing Drainage Conditions**

Historic drainage conditions are depicted in Figures EX1 and EX2. There are no existing drainage facilities within or adjacent to the site. The existing site is characterized by two large drainage retention areas within the site, represented by the hatch patterns on Sheet EX2. Off-site flows from Basins OA1-OA3 combine with on-site drainage from Basin A, draining to the existing depression within Basin A on the west side of the parcel. As shown on Sheet EX1, the existing upstream basins have several stock ponds and retention areas. There is currently no culvert for drainage to cross the low point in Davis Road at the north boundary of the Falcon Acres site. Based on the topography, overflows from Basin OA1 would overtop Davis Road and flow south into Basin A.

Off-site flows from Basins OA1, OA2.1, OA2.2, and OA3 combine with on-site flows at the existing retention area within Basin A, with calculated historic peak flows of  $Q_5 = 2.0$  cfs and  $Q_{100} = 78.8$  cfs at Design Point A.

The westerly retention area (Retention Area A) within the Falcon Acres site currently has a storage volume of approximately 91.6 acre-feet between the 6528 and 6536 contours. Overflows from this retention area would drain northeasterly to Basin B.

Off-site flows from Basin OB1 combine with on-site drainage from Basin B, draining to the existing depression within Basin B on the east side of the parcel.

Off-site flows from Basin OB1 combine with on-site flows at the existing retention area within Basin B, with calculated historic peak flows of  $Q_5 = 0.04$  cfs and  $Q_{100} = 2.8$  cfs at Design Point B.

The easterly retention area (Retention Area B) has a storage volume of approximately 6.9 acre-feet between the 6528 and 6530 contours. Overflows from Retention Area B would drain northeasterly towards the intersection of Curtis Road and Davis Road.

Based on the substantial retention volume within the site, no 100-year flows would be expected to reach Design Point #1 at the northeast corner of the site. In the unlikely event the existing retention ponds were completely full, overflows from Basin A would flow northeasterly, combining with flows from Basin B at Design Point #1, with calculated historic peak flows (SCS Method) of  $Q_5 = 1.9$  cfs and  $Q_{100} = 68.6$  cfs. As noted in Appendix B, the calculated flows for off-site basins with retention ponds have incorporated an SCS runoff curve number of 50 based on the existence of numerous upstream retention areas. Historic overflows from the Falcon Acres parcel would tend to overtop Curtis Road and flow to an existing depression on the parcel at the southeast corner of Curtis Road and Davis Road.

## **2. Developed Drainage Conditions**

The developed drainage basins and projected flows are shown in the Developed Drainage and Erosion Control Plan (Figure D1, Appendix A). In the developed condition, Basin A has been divided into sub-basins A1 and A2 by the proposed public road within the site. Off-site flows from Basin OA2.1 and OA2.2 will combine with on-site drainage from Sub-Basins A1 and A2, draining to a new culvert crossing at the low point of the proposed roadway profile. Developed peak flows at Design Point A1 are projected to be  $Q_5 = 1.4$  cfs and  $Q_{100} = 54.6$  cfs. A proposed culvert (36-inch RCP) will cross the new public road at Design Point A1.

Given the lack of any existing drainage facility crossing the low point in Davis Road, a future 24-inch culvert is recommended at Design Point OA1 prior to paving this off-site roadway. An 18-inch private driveway culvert will be installed across the private shared

driveway (Satellite View) south of Design Point OA1. Another 21-inch private driveway culvert will be constructed across Moonglow Heights at Design Point A3.1 to convey drainage across the retention area split by the new shared driveway.

Off-site flows from Basins OA1-OA3 will continue to combine with flows from Basins A1-A3 in the existing "Retention Area A" on the west side of the site. Off-site flows from Basins OA1, OA2.1, OA2.2, and OA3 will continue to combine with on-site flows from Basins A1-A3.2 at the existing retention area within Basin A, with calculated developed peak flows of  $Q_5 = 2.3$  cfs and  $Q_{100} = 89.8$  cfs at Design Point A.

This retention area has a bottom elevation of 6528.0 and the existing saddle northeast of this area has an elevation of approximately 6536.0, which would be the natural overflow point from this area. Channel A3 is proposed to provide an overflow swale northeasterly from Retention Area A to Retention Area B. This channel will be excavated to an elevation of 6533.5, and a drainage easement will encompass ground elevations within Area A up to the grade of 6534.0 to preclude building anywhere within the retention area.

The Denver Urban Drainage and Flood Control District (UDFCD) has adopted criteria requiring stormwater retention ponds to have a storage volume of 1.5 times the 24-hour, 100-year volume. As detailed in Appendix C, the calculated 100-year, 24-hour retention volume for Design Point A is 64.8 acre-feet. The available retention storage volume up to the 6533.5 contour level within Basin A is 47.3 acre-feet, which is approximately equal to the calculated 100-year storage volume requirement of 48.3 acre-feet (based on a 24-hour retention volume with safety factor of 1.5 per UDFCD criteria). Overflow channels will be provided to safely convey overflows or back-to-back storm events to existing downstream swales.

Off-site flows from Basin OB1 will continue to combine with on-site drainage from Basin B, draining to the existing "Retention Area B" on the east side of the site. Off-site flows from Basin OB1 will continue to combine with on-site flows at the existing retention area within Basin B, with calculated developed peak flows of  $Q_5 = 1.7$  cfs and  $Q_{100} = 11.7$  cfs at Design Point B.

This retention area has a bottom elevation of 6528.0 and the existing overflow swale northeast has an elevation of approximately 6530.0. A drainage easement will encompass ground elevations within Area B up to the grade of 6530 to preclude building within the retention area.

As detailed in Appendix C, the calculated 100-year, 24-hour retention volume for Design Point B is 2.3 acre-feet, which is below the available retention storage volume of 2.8 acre-feet.

As with the historic conditions, no 100-year flows would be expected to reach Design Point #1 based on the substantial retention volume within the site. In the unlikely event the

existing retention ponds were completely full, overflows from off-site Basins OA1-OA3 and OB1 will combine with flows from on-site Basins A and B at Design Point #1, with developed peak flows (SCS Method) of  $Q_5 = 2.4$  cfs and  $Q_{100} = 81.1$  cfs.

The proposed rural residential lot layout has been designed to maintain the two existing drainage retention areas, while providing an overflow channel to the northeast. Given the lack of any existing drainage facility crossing the low point on the south side of Davis Road at the Curtis Road intersection, a culvert is recommended at this location. The proposed culvert will be a 14'x23" elliptical (HERCP) culvert sized to convey overflows only from the on-site retention areas (beyond 100-year flows).

As depicted on Sheet EX1, the off-site parcel to the east also has an existing depression which serves as a drainage retention area. The proposed drainage approach of maintaining the existing drainage retention areas within the Falcon Acres parcel should maintain conditions that mimic pre-development hydrology downstream of the site.

### C. Comparison of Developed to Historic Discharges

Based on the hydrologic calculations in Appendix B, the total developed flow from the site will remain unchanged based on the existing retention volumes. If the existing retention volume were excluded from the analysis, the total developed flow would exceed historic flow from the site by a negligible amount. The increase in developed flow will be mitigated by maintaining the existing on-site drainage retention areas. The comparison of developed to historic discharges at key design points is summarized as follows:

Design Point	Historic Flow			Developed Flow			Comparison of Developed to Historic Flow ( $Q_5\%/Q_{100}\%$ )
	Area (ac)	$Q_5$ (cfs)	$Q_{100}$ (cfs)	Area (ac)	$Q_5$ (cfs)	$Q_{100}$ (cfs)	
I (with Retention)	766.2	0	0	766.2	0	0	(no change)
I (w/o Retention)	766.2	1.9	68.6	766.2	2.4	81.1	126% / 118% (increase)

The total developed storm runoff downstream of the proposed subdivision will be maintained at historic levels by routing flows through two existing retention ponds within the site. The retention volume has been sized to retain the calculated 24-hour, 100-year storm discharge from the developed basins within the site, as detailed in Appendix D. Overflow swales will be provided to convey major storm discharges downstream following historic drainage patterns. Based on the drainage concept of protecting the existing on-site retention areas, the proposed development will have a negligible downstream drainage impact.

## **D. On-Site Drainage Facility Design**

Developed sub-basins and proposed drainage improvements are depicted in the enclosed Drainage Plan (Sheet D1). In accordance with El Paso County standards, new roadways will be graded with a minimum longitudinal slope of 1.0 percent.

On-site drainage facilities will consist of roadside ditches, grass-lined channels, and culverts. Hydraulic calculations for sizing of drainage facilities are enclosed in Appendix C and design criteria are summarized as follows:

### **1. Culverts**

The internal road system will be graded to drain roadside ditches to low points along the road profile, where cross-culverts will convey developed flows into grass-lined channels following historic drainage paths. Culvert pipes have been specified as reinforced concrete pipe (RCP) with a minimum diameter of 18-inches. Culvert sizes have been identified based on a maximum headwater-to-depth ratio (HW/D) of 1.0 for the minor (5-year) design storm. Final culvert design has been performed utilizing the FHWA HY-8 software package to perform a detailed analysis of inlet and outlet control conditions, meeting El Paso County criteria for allowable overtopping. Riprap outlet protection will be provided at all culverts. Culvert sizing parameters are summarized in Appendix C.

### **2. Open Channels**

Drainage easements have been dedicated along major drainage channels and existing depressions within the site, following historic drainage paths through the subdivision. Proposed channels will generally be grass-lined channels designed to convey 100-year flows, with a trapezoidal cross-section, variable bottom width and depth, 4:1 maximum side slopes, 1-foot minimum freeboard, and a minimum slope of 0.5 percent.

The proposed drainage channels have been sized utilizing Manning's equation for open channel flow, assuming a friction factor ("n") of 0.030 for dry-land grass channels. Maximum allowable velocities have been evaluated based on El Paso County drainage criteria, typically allowing for a maximum 100-year velocity of 5 feet per second. The proposed channels will be seeded with native grasses for erosion control. Ditch flows will be diverted to drainage channels at the nearest practical location to minimize excessive roadside ditch sizes. Detailed channel hydraulic calculations are provided in Appendix C.

Drainage swales crossing proposed lots and existing drainage retention areas within the site have been placed in drainage easements, with variable widths based on the calculated 100-year water surface elevations and retention area configuration. Based on the proposed channel section (4' bottom, 2' deep, 4:1 side slopes) and calculations in Appendix C, a minimum drainage easement width of 30 feet is required for the overflow swales from each of the retention ponds.

## **E. Anticipated Drainage Problems and Solutions**

The drainage plan for this subdivision includes a system of roadside ditches, channels, and culverts to convey developed flows through the site. The primary drainage problems anticipated within this development will consist of maintenance of these drainage channels and culverts. Care will need to be taken to implement proper erosion control measures in the proposed roadside ditches, channels, and swales. Ditches have been designed to meet allowable velocity criteria. Seeding will be the primary erosion control method within the on-site ditches and channels. Erosion control blankets have been specified where necessary. Proposed drainage facilities outside the public right-of-way will be owned and maintained by the subdivision HOA or individual lot owners.

## **V. EROSION CONTROL / SEDIMENT CONTROL**

Best management practices (BMP's) will be implemented for erosion control during construction. Erosion control measures will include installation of silt fence at the toe of disturbed slopes, straw or hay bales protecting drainage ditches, vehicle tracking control pads at access points, and revegetation of disturbed areas. Cut slopes will be stabilized during excavation as necessary and vegetation will be re-established as soon as possible for stabilization of the graded areas. The two drainage retention areas will serve as permanent water quality BMP's, minimizing adverse drainage impacts to downstream areas.

## **VI. COST ESTIMATE AND DRAINAGE FEES**

The estimated cost for drainage improvements serving the Falcon Acres Subdivision is approximately \$36,800, as detailed in Appendix D.

The site lies completely within the Livestock Company Drainage Basin (CHWS-0400), which has a 2007 basin fee of \$11,842 per impervious acre and a bridge fee of \$141 per impervious acre. The calculation of applicable drainage basin fees is summarized as follows:

Average residential lot size = 5 acre/lot (gross density)  
Residential Area = 47.577 acres  
Percent impervious = 7% (per El Paso County guidelines, Table 3-1)  
Total Impervious area = (7% \* 47.577) = 3.33 ac.  
Adjusted Impervious area = (3.33 ac) \* 75% = 2.50 ac.  
(Includes 25% reduction on drainage fees for 5-acre lots)  
**Drainage Basin Fee = (2.5 ac.) @ \$11,842/ac. = \$29,605.00**  
**Bridge Fee = (3.33 ac.) @ \$141/ac. = \$ 469.53**  
**Total Calculated Fee = \$30,074.53**

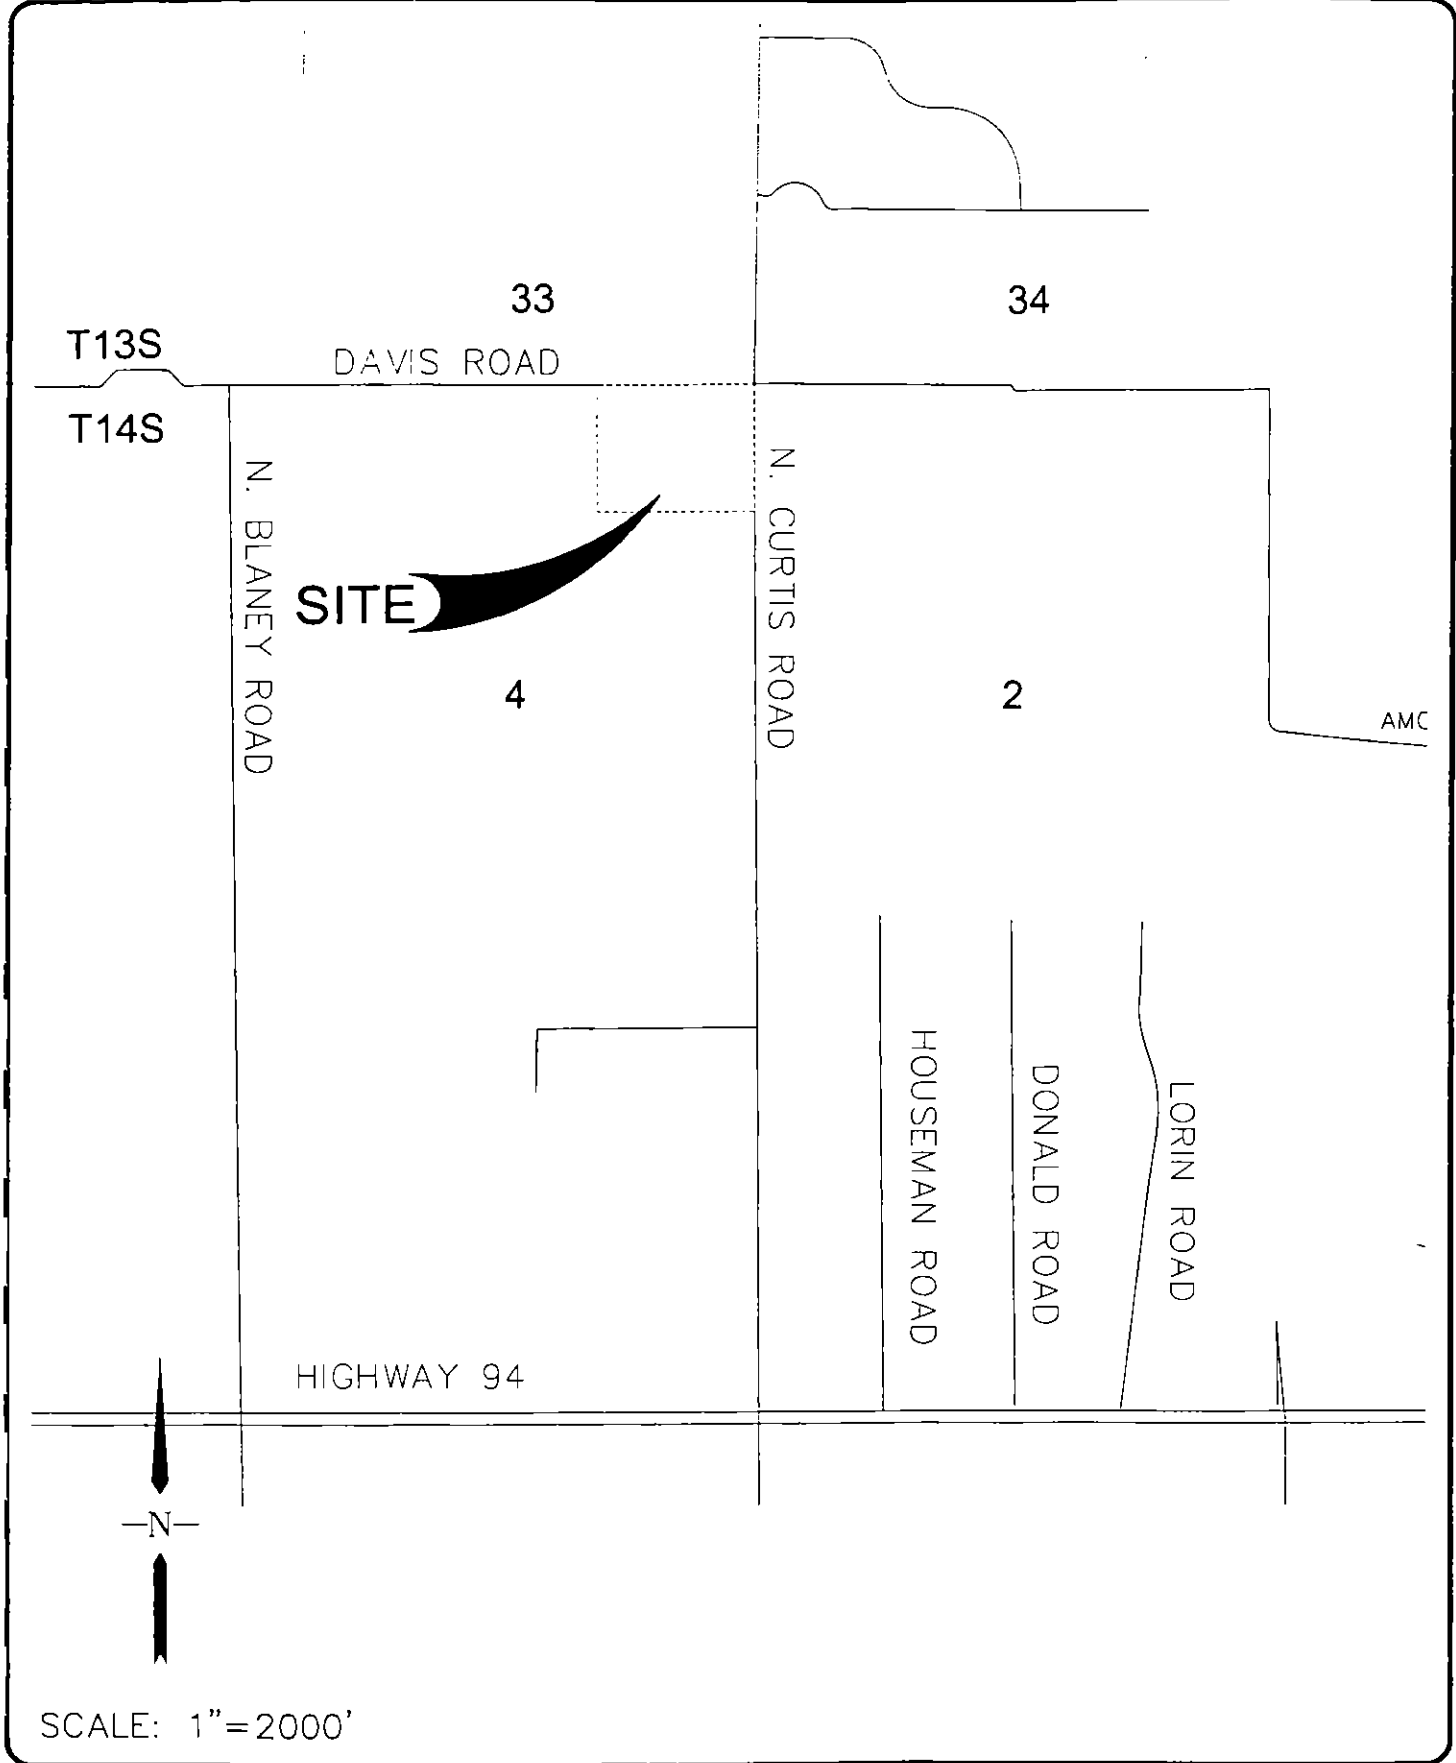

## **VI. SUMMARY**

Falcon Acres is a proposed subdivision consisting of 8 rural residential lots located south of Falcon in El Paso County, Colorado. Development of the proposed 47.6-acre Falcon Acres Subdivision will result in a negligible increase in undetained developed runoff from the site, which will be mitigated by maintaining two existing drainage retention areas within the site.

The proposed drainage patterns will remain consistent with historic conditions, and new drainage facilities will be constructed on-site to El Paso County standards to safely convey runoff to adequate outfalls. Maintenance of the existing drainage retention areas, in conjunction with proper erosion control measures, will ensure that there will be no adverse drainage impacts from this development to downstream landowners or parcels.

(EL PASO COUNTY SOILS MAP NO. 18)

SCS SOILS MAP

FALCON ACRES  
SUBDIVISION

FIGURE B

JPS PROJ NO. 020506

Almost all areas of this soil are used as rangeland. A few areas of crops such as alfalfa and corn are grown under sprinkler irrigation.

This soil is well suited to the production of native vegetation suitable for grazing. It is best suited to deep-rooted grasses. The native vegetation is mainly cool- and warm-season grasses such as western wheatgrass, side-oats grama, and needleandthread.

Proper range management is needed to prevent excessive removal of the plant cover. Interseeding is used to improve the existing vegetation. Deferment of grazing in spring increases plant vigor and soil stability. Properly locating livestock watering facilities helps to control grazing.

Windbreaks and environmental plantings are fairly well suited to this soil. Blowing sand is the main limitation for the establishment of trees and shrubs. The soil is so loose that trees need to be planted in shallow furrows and plant cover needs to be maintained between the rows. Supplemental irrigation may be needed to insure survival. Trees that are best suited and have good survival are Rocky Mountain juniper, eastern redcedar, ponderosa pine, and Siberian elm. Shrubs that are best suited are skunkbush sumac, lilac, and Siberian peashrub.

This soil is suited to wildlife habitat. It is best suited to openland and rangeland wildlife habitat. Rangeland wildlife, such as pronghorn antelope, can be encouraged by developing livestock watering facilities, properly managing livestock grazing, and reseeding range where needed.

This soil has good potential for use as homesites. The main limitation of this soil for roads and streets is frost action potential. Special designs for roads are needed to minimize this limitation. Practices are needed to control soil blowing and water erosion on construction sites where the plant cover has been removed. Capability subclass VIe, nonirrigated.

**96—Truckton sandy loam, 0 to 3 percent slopes.** This deep, well drained soil formed in alluvium and residuum derived from arkosic sedimentary rock on uplands. Elevation ranges from 6,000 to 7,000 feet. The average annual precipitation is about 15 inches, the average annual air temperature is about 47 degrees F, and the average frost-free period is about 135 days.

Typically, the surface layer is grayish brown sandy loam about 5 inches thick. The next layer is dark grayish brown sandy loam about 3 inches thick. The subsoil is brown sandy loam about 16 inches thick. The substratum is light yellowish brown coarse sandy loam to a depth of 60 inches or more.

Included with this soil in mapping are small areas of Blakeland loamy sand, 1 to 9 percent slopes; Bresser sandy loam, 0 to 3 percent slopes; Ellicott loamy coarse sand, 0 to 5 percent slopes; and Ustic Torrifluvents, loamy.

Permeability of this Truckton soil is moderately rapid. Effective rooting depth is 60 inches or more. Available water capacity is moderate. Surface runoff is slow, and the hazards of erosion and soil blowing are moderate.

This soil is used mainly for cultivated crops. It is also used for livestock grazing, for wildlife habitat, and as homesites.

Crops are commonly grown in combination with summer fallow because moisture is insufficient for annual cropping. Alfalfa can also be grown on this soil. When this soil is used as cropland, crop residue management and minimum tillage are necessary conservation practices.

This soil is well suited to the production of native vegetation suitable for grazing (fig. 7). It favors deep-rooted grasses. The native vegetation is mainly cool- and warm-season grasses such as western wheatgrass, side-oats grama, and needleandthread.

Proper range management is needed to prevent excessive removal of the plant cover. Interseeding is used to improve the existing vegetation. Deferment of grazing in spring increases plant vigor and soil stability. Properly locating livestock watering facilities helps to control grazing.

Windbreaks and environmental plantings generally are suited to this soil. Soil blowing is the main limitation to the establishment of trees and shrubs. This limitation can be overcome by cultivating only in the tree rows and leaving a strip of vegetation between the rows. Supplemental irrigation may be needed when planting and during dry periods. Trees that are best suited and have good survival are Rocky Mountain juniper, eastern redcedar, ponderosa pine, Siberian elm, Russian-olive, and hackberry. Shrubs that are best suited are skunkbush sumac, lilac, and Siberian peashrub.

This soil is suited to wildlife habitat. It is best suited to habitat for openland and rangeland wildlife. In cropland areas, habitat favorable for ring-necked pheasant, mourning dove, and many nongame species can be developed by establishing areas for nesting and escape cover. For pheasant, undisturbed nesting cover is vital and should be provided in plans for habitat development. This is especially true in areas of intensive farming. Rangeland wildlife, such as pronghorn antelope, can be encouraged by developing livestock watering facilities, properly managing livestock grazing, and reseeding range where needed.

This soil has good potential for use as homesites. The main limitation of this soil for roads and streets is frost action potential. Special designs for roads are needed to overcome this limitation. Capability subclasses IIIe, nonirrigated, and IIe, irrigated.

**97—Truckton sandy loam, 3 to 9 percent slopes.** This deep, well drained soil formed in alluvium and residuum derived from arkosic sedimentary rock on uplands. Elevation ranges from 6,000 to 7,000 feet. The average annual precipitation is about 15 inches, the average annual air temperature is about 47 degrees F, and the average frost-free period is about 135 days.

Typically, the surface layer is grayish brown sandy loam about 5 inches thick. The next layer is dark grayish brown sandy loam about 3 inches thick. The subsoil is brown sandy loam about 16 inches thick. The substratum is light yellowish brown coarse sandy loam to a depth of 60 inches or more.

Included with this soil in mapping are small areas of Blakeland loamy sand, 1 to 9 percent slopes; Bresser sandy loam, 3 to 5 percent slopes; and Truckton sandy loam, 0 to 3 percent slopes. Also included are small areas of soils that have arkosic sandstone or shale at a depth of less than 40 inches.

Permeability of this Truckton soil is moderately rapid. Effective rooting depth is 60 inches or more. Available water capacity is moderate. Surface runoff is slow to medium, and the hazards of erosion and soil blowing are moderate.

More than half of this soil is used as rangeland, for wildlife habitat, and as homesites. The rest, consisting of the less sloping areas, is used for wheat and sorghum. Rangeland or pastureland is the most suitable use because the permanent plant cover protects the soil.

This soil is well suited to the production of native vegetation suitable for grazing. Native vegetation is mainly cool- and warm-season grasses such as western wheatgrass, side-oats grama, and needleandthread.

Proper range management is needed to prevent excessive removal of the plant cover from this soil. Interseeding improves the existing vegetation. Deferment of grazing in spring increases plant vigor and soil stability. Properly locating livestock watering facilities helps to control grazing.

Windbreaks and environmental plantings generally are well suited to this soil. Soil blowing is the main limitation to the establishment of trees and shrubs. This limitation can be overcome by cultivating only in the tree rows and leaving a strip of vegetation between the rows. Supplemental irrigation may be needed when planting and during dry periods. Trees that are best suited and have good survival are Rocky Mountain juniper, eastern redcedar, ponderosa pine, Siberian elm, Russian-olive, and hackberry. Shrubs that are best suited are skunkbush sumac, lilac, and Siberian peashrub.

This soil is suited to wildlife habitat. It is best suited to habitat for openland and rangeland wildlife. In cropland areas, habitat favorable for ring-necked pheasant, mourning dove, and many nongame species can be developed by establishing areas for nesting and escape cover. For pheasant, undisturbed nesting cover is vital and should be provided for in plans for habitat development. Rangeland wildlife, such as pronghorn antelope, can be encouraged by developing livestock watering facilities, properly managing livestock grazing, and reseeding range where needed.

The main limitation of this soil for construction is frost-action potential. Special designs for roads are needed to overcome this limitation. Because of the sandy nature of the soil, practices must be provided to minimize surface runoff and thus keep erosion to a minimum. Access roads must have adequate cut-slope grade and be provided with drains to control surface runoff. Capability subclasses are, nonirrigated, and IVe, irrigated.

18—Truckton-Blakeland complex, 9 to 20 percent slopes. These strongly sloping to moderately steep soils

are on uplands. Elevation ranges from 6,000 to 7,000 feet. The average annual precipitation is about 15 inches, the average annual air temperature is about 47 degrees F, and the average frost-free period is about 135 days.

The Truckton soil makes up about 60 percent of the complex, the Blakeland soil about 25 percent, and other soils about 15 percent.

Included with these soils in mapping are areas of Bresser sandy loam, 5 to 9 percent slopes, and Yoder gravelly sandy loam, 8 to 25 percent slopes.

The Truckton soil is deep and well drained. It formed in alluvium and residuum weathered from arkosic sedimentary rock. Typically, the surface layer is grayish brown sandy loam about 5 inches thick. The next layer is dark grayish brown sandy loam about 3 inches thick. The subsoil is brown sandy loam about 16 inches thick. The substratum is light yellowish brown coarse sandy loam to a depth of 60 inches or more.

Permeability of the Truckton soil is moderately rapid. Effective rooting depth is 60 inches or more. Available water capacity is moderate. Surface runoff is medium to rapid, and the hazard of erosion is moderate to high. Soil slippage is common on the upper part of slopes.

The Blakeland soil is deep and somewhat excessively drained. It formed in arkosic sandy alluvium and eolian sediment derived from arkosic sedimentary rock. Typically, the surface layer is dark grayish brown loamy sand about 11 inches thick. The underlying material is brown loamy sand about 16 inches thick; it grades to pale brown sand that extends to a depth of 60 inches or more.

Permeability of the Blakeland soil is rapid. Effective rooting depth is 60 inches or more. Available water capacity is low to moderate. Surface runoff is medium, and the hazard of erosion is moderate to high, and the hazard of soil blowing is high. Soil slippage is common on the upper part of slopes.

The soils in this complex are used for grazing livestock and wildlife habitat.

These soils are suited to the production of native vegetation suitable for grazing. The native vegetation is dominantly western wheatgrass, side-oats grama, and needleandthread.

Proper range management is needed to prevent excessive removal of the plant cover from these soils. Interseeding improves the existing vegetation. Deferment of grazing in spring improves plant vigor and soil stability. Properly locating livestock watering facilities helps to control grazing.

Soil blowing is the main limitation for the establishment of trees and shrubs on these soils. This limitation can be overcome by cultivating only in the tree rows and leaving a strip of vegetation between the rows. Trees need to be planted in shallow furrows on the Blakeland soil because of its loose, sandy surface layer. Supplemental irrigation may be needed to insure survival. Trees that are best suited and have good survival are Rocky Mountain juniper, eastern redcedar, ponderosa pine, Siberian elm, Russian-olive, and hackberry. Shrubs that are best suited are skunkbush sumac, lilac, and Siberian peashrub.

dirt	72*	82	87	89

1/ For a more detailed description of agricultural land use curve numbers, refer to the National Engineering Handbook (U.S. Dept. of Agriculture, Soil Conservation Service, 1972).

2/ Curve numbers are computed assuming the runoff from the house and driveway is directed towards the street with a minimum of roof water directed to lawns where additional infiltration could occur.

3/ The remaining pervious areas (lawn) are considered to be in good pasture condition for these curve numbers.

\* Not to be used wherever overlot grading or filling is to occur.

FOMO4400	Monument Creek		Jackson Creek	\$5,066	\$0
FOMO4800	Monument Creek		Tanchout Creek	\$3,518	\$528

- The miscellaneous drainage fee previous to September 1999 resolution was the average of all drainage fees for basins with Basin Planning Studies performed within the last 14 years.
- Interim Drainage Fees are based upon draft Drainage Basin Planning Studies or the Drainage Basin Identification and Fee Estimation Report. (Best available information available for setting a fee)
- This is an interim fee and will be adjusted when a DBPS is completed. In addition to the Drainage Fee of \$15,000 a surety in the amount of \$7,000 per impervious acre shall be provided to secure payment of additional fees in the event that the DBPS results in a fee greater than \$15,000. Fees paid in excess of the future revised fee will be reimbursed. See Resolution 08-325, September 14, 2008.

## DRAINAGE REPORT STATEMENT

### Design Engineer's Statement

This attached drainage plan and report were prepared under my direction and supervision and are correct to the best of my knowledge and belief. Said drainage report has been prepared according to the criteria established by the County for drainage reports and said report is in conformity with the master plan of the drainage basin. I accept responsibility for any liability caused by any negligent acts, errors or omissions on my part in preparing this report.

---

L DUCETT, P.E. 32339

# FINAL DRAINAGE REPORT ADDENDUM #1 FOR FALCON ACRES EL PASO COUNTY, COLORADO

## PURPOSE AND JUSTIFICATION

The purpose of this Final Drainage Report Addendum #1 is to update the construction cost opinion, drainage & bridge fees, and FEMA floodplain statement for the previously approved drainage report titled “Final Drainage Report for Falcon Acres Subdivision” dated June 25, 2007 prepared by JPS Engineering.

## UPDATED CONSTRUCTION COST OPINION

	<b>DRAINAGE IMPROVEMENTS</b>	Quantity	Units	Unit Cost	<b>Total Cost</b>
506	Riprap Aprons (d <sub>50</sub> = 12")	25	Tons	\$83	\$2,075
603	23"x14" HERCP Culvert w/ FES	88	LF	\$81	\$7,128
603	36" RCP Culvert w/ FES	62	LF	\$124	\$7,688
	<b>SUBTOTAL</b>				<b>\$16,891</b>

## UPDATED DRAINAGE & BRIDGE FEES

This currently unplatted site is in the Livestock Company Drainage Basin. The site is 49.23 acres. Appendix L of the Drainage Criteria Manual 1 Addendum states that for single-family 5 acre lots, an impervious percentage of 7% can be used. The combined Drainage Fees (2021) are due prior to final plat recordation.

<b>Fee Type</b>	<b>% Imp.</b>	<b>Parcel Area (acre)</b>	<b>Imp. Area (acre)</b>	<b>Fee per Imp Acre</b>	<b>Mod %</b>	<b>Fee Cost</b>
Drainage	7	49.23	3.45	\$18,273	100	\$63,042
Bridge	7	49.23	3.45	\$217	100	\$749
				<b>Total</b>		\$114,165

## UPDATED FLOODPLAIN STATEMENT

According to FEMA’s FIRM No. 08041CO785G (eff. 12/7/2018), the proposed development is within an area designated as Zone X, having minimal flood hazard.

**FEMA MAP**

## Legend

SEE FIS REPORT FOR DETAILED LEGEND AND INDEX MAP FOR FIRM PANEL LAYOUT

SPECIAL FLOOD HAZARD AREAS		Without Base Flood Elevation (BFE) Zone A, V, A99
		With BFE or Depth Zone AE, AO, AH, VE, AR
		Regulatory Floodway
OTHER AREAS OF FLOOD HAZARD		0.2% Annual Chance Flood Hazard, Areas of 1% annual chance flood with average depth less than one foot or with drainage areas of less than one square mile Zone X
		Future Conditions 1% Annual Chance Flood Hazard Zone X
		Area with Reduced Flood Risk due to Levee. See Notes. Zone X
		Area with Flood Risk due to Levee Zone D
OTHER AREAS		NO SCREEN Area of Minimal Flood Hazard Zone X
		Effective LOMRs
		Area of Undetermined Flood Hazard Zone D
GENERAL STRUCTURES		Channel, Culvert, or Storm Sewer
		Levee, Dike, or Floodwall
OTHER FEATURES		20.2 Cross Sections with 1% Annual Chance Water Surface Elevation
		17.5
		Coastal Transect
		Base Flood Elevation Line (BFE)
		Limit of Study
		Jurisdiction Boundary
		Coastal Transect Baseline
		Profile Baseline
MAP PANELS		Digital Data Available
		No Digital Data Available
		Unmapped

The pin displayed on the map is an approximate point selected by the user and does not represent an authoritative property location.

This map complies with FEMA's standards for the use of digital flood maps if it is not void as described below. The basemap shown complies with FEMA's basemap accuracy standards

The flood hazard information is derived directly from the authoritative NFHL web services provided by FEMA. This map was exported on **8/1/2021 at 4:25 PM** and does not reflect changes or amendments subsequent to this date and time. The NFHL and effective information may change or become superseded by new data over time.

This map image is void if the one or more of the following map elements do not appear: basemap imagery, flood zone labels, legend, scale bar, map creation date, community identifiers, FIRM panel number, and FIRM effective date. Map images for unmapped and unmodernized areas cannot be used for regulatory purposes.
