SUBJECT: Drainage Plan and Report

All About Outdoor Storage PPR-16-037

Transmitted herewith for your review and approval is the drainage plan and report for All About Outdoor Storage at 16140 Old Denver Road in El Paso County. This report will accompany the change in use request for subject development, as requested in you review letter of January 6, 2017. It has been revised in accordance with our meeting with you and Elizabeth Nijkamp April 17, 2017, subsequent additional surveys performed at your request, and your comments of January 5, 2018, January 28, 2020, March 12, 2020, November 16, 2020, and February 18, 2021. This plan will reflect the anticipated ultimate development of the entire site.

Please contact me if I may provide any further information.

1. ENGINEER'S STATEMENT:

The attached drainage plan and report were prepared under my direction and supervision and are correct to the best of my knowledge and belief. Said drainage report has been prepared according to the criteria established by the County for drainage reports and said report is in conformity with the applicable master plan of the drainage basin. I accept responsibility for any liability caused by any negligent acts, errors or omissions on my part in preparing this report.

4. LOCATION AND DESCRIPTION:

All About Outdoor Storage is located at 16140 Old Denver Road adjacent to the Southerly City limits for the Town of Monument in Section 26, T.11S., R.67W. of the 6th P.M. in El Paso County. A change is land use from a landscape rock yard to a RV storage use was requested, and this report is a result of the 1st County review letter of January 6, 2017. The effect of this change in use is analyzed.

The site is located on Teachout Creek, and unstudied drainage basin lying south of Dirty Woman Creek. None of the requirements in the Dirty Woman Creek MDBPS affect this site. This and adjacent sites drain westerly to the Union Pacific Railroad right of way and southerly into the Teachout Creek Creek crossing, which immediately discharges into Monument Creek. The drainage outfall from this site remains on private ground east of the railroad right of way.

The front portion of the total property is leased and used by All About Outdoor Storage, and the rear is used for equipment storage by another owner, as shown on the drainage plan. The existing detention pond near the southwest corner was constructed in 1986; however the County files could not be found. There is no history of drainage problems with the existing construction and it does not appear that the outlet works or spillway have discharged since construction.

5. FLOOD PLAIN STATEMENT:

This subdivision is not within the limits of a flood plain or flood hazard area, according to FEMA map panel number 08041C0286 G, dated December 7, 2018, a copy of which is enclosed for reference.

6. METHOD AND CRITERIA:

The method used for all computations is that specified in the City-County Drainage Criteria Manual, using the rational method for areas of the size of the development. Detention computations are based on UD-Detention work sheets, for existing and full spectrum detention conditions. All computations are enclosed for reference and review. The approach is to use as many of the existing facilities as possible, consistent with the referenced meetings with El Paso County personnel.

The soils in the subdivision have been mapped by the local USDA/SCS office, and a soils map and interpretation sheet are enclosed for reference. All soils in this area are of hydrologic group "B" within the affected area.

7. DESCRIPTION OF RUNOFF:

The major change in the development resulting from the proposed change of use is a change in the pavement over the storage site from gravel to a shaved asphalt surface, in order to mitigate dust. The site is totally graded and runoff is westerly to an existing detention pond in the southwest corner adjacent to the D&RG railroad right of way. Existing and proposed runoffs are computed contrasting the two pavement types and the detention pond is analyzed in accordance with its intended use as a full spectrum extended detention basin.

Basin A consists of the total All About Outdoor Storage property and sheet flows to the westerly boundary where the historic runoff of 15.9 cfs / 31.8 cfs (5-year / 100- year runoffs), increases to 22.7 cfs / 49.9 cfs. The historic gravel surface of this site is analyzed to represent total shaved asphaltic pavement, rolled and compacted in place over the entire property, including the entrance roadway. This runoff will sheet flow in the historic manner into the equipment storage portion of the site. No change in grading will be required, nor will drainage structures of any sort be required.

Basis B consists of the majority of the equipment storage portion of the property, and is anticipated to develop in similar manor to Basin A, consisting of a native gravel surface. It now has numerous pieces of

All About Outdoor Storage Drainage Plan and Report

construction equipment in storage but will be configured for vehicle storage similar to that in Basin A. An existing metal building constructed in 1999 will remain in place. The total runoff will sheet flow to the existing detention pond in the southwest corner of the site. The combined historic runoff at the pond site of 19.1 cfs / 41.5 cfs will be increased to 22.4 cfs / 49.6 cfs, based on an anticipated total impervious ratio of 70%. No additional drainage provisions will be required other than normal maintenance of existing facilities.

The existing detention pond was originally constructed in 1986 as a detention basin for peak flow mitigation, along with those of similar structures on the two adjacent northerly lots. No design details are on file. The total storage in the pond to the spillway is 0.155 acre feet, with 0.559 acre feet available to the top of the embankment. There are two 8-inch drains stubbed into the pond, exiting into a 5 foot diameter vertical RCP outlet works, with an 8- inch PVC outlet works, discharging onto the owner's property to the south. The existing pond shows no sign of erosion at the spillway or along the embankment, and there is no sign that the outlet pipe has ever carried runoff. It apparently has functioned adequately since its construction in 1986, giving it a current history of nearly 35 years adequate service. Because of this, an infiltration test was taken by Vivid geotechnical, the results of which are enclosed. The anticipated infiltration values are incorporated into the design sheets.

The existing outlet works will be replaced with a full spectrum outlet works as prescribed by the Denver Urban drainage criteria. The details of the outlet are included with the drainage plans and the computation sheets are enclosed, based on the geometry of the proposed pond. As shown the pond has a capacity of 1.503 acre feet at elevation 6787. The water quality capture volume is 0.193 AF, the EURV is 0.591 AF. The required detention for the 100-year storm is 1.049 AF. Corresponding water surface values are shown on the outlet structure detail sheet. The maximum water surface for the 100-year storm is at elevation 84.77, and the emergency spillway is set at elevation 86.00. The detention computations show a peak outfall of 14.9 CFS for the pond, well below the historic runoff value of 41.5 cfs. Based on the spillway geometry type VL riprap is provided. An 18 inch RCP outlet is proposed with a reectangular orifice plate.

The outfall of the 18" RCP outlet pipe is within a small triangular portion of the boundary of this parcel as shown on the drainage plan. A channel runs southerly from there through a dense willow patch and outside the railroad right of way to the Teachout Creek channel that crosses the railroad into Monument Creek as shown on the enclosed FEMA map. Computations sheets are enclosed showing that the channel is stable through the willow thicket and needs no improvement.

Access ramps are to be provided as shown on the drainage plan to provide County required construction vehicular access to the pond for maintenance.

Basin "C" consists of an area adjacent to the D&RG right of way that was constructed to provide a dike routing the runoff into the pond, and is a range land type cover. The runoff is 0.1cfs /0.5cfs into the right of way

8. FOUR STEP PROCESS

The following process has been followed to minimize adverse impacts of urbanization

A. Employ Reduction Practiced: The scope of the development has been minimized consistent with zoning requirements to present the minimum footprint in providing a commercial development of the type proposed by the owner. The pavements chosen create a minimum of runoff consistent with the requirement amount of protection. The undisturbed portions are to be landscaped to increase the pervious percent.

B. Stabilize Drainageways: The site will be graded to route the runoff over improved installations to provide channel stabilizing in the natural erosive material over the site. Improvements above those shown on the approved plans will be made on an as-needed basis. Discharge from the site will be into a stable

All About Outdoor Storage Drainage Plan and Report

channel, being the historic discharge location. An analysis of this channel is included in the computations. There will be no adverse affect on downstream developments as a result of this subdivision

<u>C. Provide Water Quality Capture Volume (WQCV):</u> The above described EDB is to be provided to provide water quality treatment and a reduced rate of discharge from the development as specified by County regulations. Details are shown on the enclosed ED-Detention work sheets, as summarized above. That portion to be graded at this time is below one acre. The WQCV will be released through the orifice plate figuration in the outlet structure.

<u>D. Consider Need for Industrial and Commercial BMP's:</u> This is a commercial RV storage site, so source control problems will be a minimum. During construction of the detention pond and site improvements, standard site specific state of the art BMP's will be employed to minimize and mitigate erosive problems. Grading and erosion control plans will be submitted for approval as required.

9. COST ESTIMATE:

All items are private.

| Item No. | Description | Quantity | Unit Cost | Cost |
|----------|----------------------------|----------|-----------|--------------|
| 1 | Pond Excavation | 1647 CY | \$ 5.00 | \$ 8,235.00 |
| 2 | Pond Embankment | 489 CY | 10.00 | 4,890.00 |
| 3 | DU EDB Outlet Structure | LS | 25,000 | 25,000.00 |
| 4 | 18" RCP | 47.20 LF | 65.00 | 3,068.00 |
| 5 | VL Riprap | 116 CY | 112.00 | 12,992.00 |
| | Subtotal Construction Cost | | | \$ 54,185.00 |
| | Engineering | 10% | | 5,418.50 |
| | Total Estimated Cost | | | \$ 59,603.50 |

9. FEES:

Fees are not applicable

10. SUMMARY

The "All About Outdoor Storage" site is a 12.090 acre commercial RV storage site. The front (east) 7.002 acre portion is now in use for that purpose, and the rear remainder is vacant storage except for the existing detention pond in the Southwest corner. The proposed drainage facilities will adequately convey, detain and outfall runoff from the site to existing sufficient downstream facilities. These facilities are designed so that the total site may be used for RV storage without further revision to the drainage plan and facilities. Site runoff and storm drain and appurtenances will not adversely affect the downstream and surrounding developments.

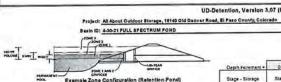

The drainage analysis has been prepared in accordance with the current City of Colorado Springs and El Paso County Drainage Criteria Manuel. Supporting information and calculations are included in this report.

Revise outlet design so the values are equal to or less than 1.0. Peak outflow must be equal to or less than predevelopment flow.

maximum bound

UD-Detention, Version 3.07 (February 2017)

Summary Stage-Area-Volume-Discharge Relationships
The user can create a summary S-A-V-D by entering the desired stage increments and the remainder of the table will populate automatically.

| Stage - Storage Description | Stage (ft) | Area [ft^2] | Area [acres] | Volume [ft^3] | Volume (ac-ft) | Total Cutflow (cfs) | |
|--------------------------------|----------------|----------------|-----------------|------------------|-------------------|---------------------------|--|
| | 177 | 10.74 | | | | | For best results, include the |
| | | | | | | | stages of all grade slope |
| | | | | | | | changes (e.g. ISV and Floor) |
| | | | | | | | from the S-A-V table on |
| | | | | | - | | Sheet 'Basin'. |
| | | | | | _ | | Also include the inverts of all |
| | | | | | | | outlets (e.g. vertical orifice, |
| | | | | | | | overflow grate, and spillway, |
| | | | | | | | where applicable). |

3.2 Time of Concentration

One of the basic assumptions underlying the Rational Method is that runoff is a function of the average rainfall rate during the time required for water to flow from the hydraulically most remote part of the drainage area under consideration to the design point. However, in practice, the time of concentration can be an empirical value that results in reasonable and acceptable peak flow calculations.

For urban areas, the time of concentration (t_c) consists of an initial time or overland flow time (t_i) plus the travel time (t_i) in the storm sewer, paved gutter, roadside drainage ditch, or drainage channel. For non-urban areas, the time of concentration consists of an overland flow time (t_i) plus the time of travel in a concentrated form, such as a swale or drainageway. The travel portion (t_i) of the time of concentration can be estimated from the hydraulic properties of the storm sewer, gutter, swale, ditch, or drainageway. Initial time, on the other hand, will vary with surface slope, depression storage, surface cover, antecedent rainfall, and infiltration capacity of the soil, as well as distance of surface flow. The time of concentration is represented by Equation 6-7 for both urban and non-urban areas.

$$t_c = t_i + t_t \tag{Eq. 6-7}$$

Where:

 t_c = time of concentration (min)

 t_i = overland (initial) flow time (min)

 t_t = travel time in the ditch, channel, gutter, storm sewer, etc. (min)

Overland (Initial) Flow Time 3.2.1

The overland flow time, t_i , may be calculated using Equation 6-8.

$$t_i = \frac{0.395(1.1 - C_5)\sqrt{L}}{S^{0.33}}$$
 (Eq. 6-8)

Where:

 t_i = overland (initial) flow time (min)

 C_5 = runoff coefficient for 5-year frequency (see Table 6-6)

L = length of overland flow (300 ft <u>maximum</u> for non-urban land uses, 100 ft <u>maximum</u> for

S = average basin slope (ft/ft)

Note that in some urban watersheds, the overland flow time may be very small because flows quickly concentrate and channelize.

3.2.2 Travel Time

For catchments with overland and channelized flow, the time of concentration needs to be considered in combination with the travel time, t_0 , which is calculated using the hydraulic properties of the swale, ditch, or channel. For preliminary work, the overland travel time, t_i , can be estimated with the help of Figure 6-25 or Equation 6-9 (Guo 1999).

$$V = C_{\nu} S_{\nu}^{0.5}$$
 (Eq. 6-9)

Where:

V = velocity (ft/s)

 C_{ν} = conveyance coefficient (from Table 6-7)

 S_w = watercourse slope (ft/ft)

Type of Land Surface C_{ν} Heavy meadow 2.5 Tillage/field 5 Riprap (not buried)* 6.5 Short pasture and lawns 7 Nearly bare ground 10 Grassed waterway 15 Paved areas and shallow paved swales 20

Table 6-7. Conveyance Coefficient, C_{ν}

For buried riprap, select C_v value based on type of vegetative cover.

The travel time is calculated by dividing the flow distance (in feet) by the velocity calculated using Equation 6-9 and converting units to minutes.

The time of concentration (t_c) is then the sum of the overland flow time (t_i) and the travel time (t_t) per Equation 6-7.

3.2.3 First Design Point Time of Concentration in Urban Catchments

Using this procedure, the time of concentration at the first design point (typically the first inlet in the system) in an urbanized catchment should not exceed the time of concentration calculated using Equation 6-10. The first design point is defined as the point where runoff first enters the storm sewer system.

$$t_c = \frac{L}{180} + 10 \tag{Eq. 6-10}$$

Where:

 t_c = maximum time of concentration at the first design point in an urban watershed (min) L = waterway length (ft)

Equation 6-10 was developed using the rainfall-runoff data collected in the Denver region and, in essence, represents regional "calibration" of the Rational Method. Normally, Equation 6-10 will result in a lesser time of concentration at the first design point and will govern in an urbanized watershed. For subsequent design points, the time of concentration is calculated by accumulating the travel times in downstream drainageway reaches.

3.2.4 Minimum Time of Concentration

If the calculations result in a t_c of less than 10 minutes for undeveloped conditions, it is recommended that a minimum value of 10 minutes be used. The minimum t_c for urbanized areas is 5 minutes.

3.2.5 Post-Development Time of Concentration

As Equation 6-8 indicates, the time of concentration is a function of the 5-year runoff coefficient for a drainage basin. Typically, higher levels of imperviousness (higher 5-year runoff coefficients) correspond to shorter times of concentration, and lower levels of imperviousness correspond to longer times of

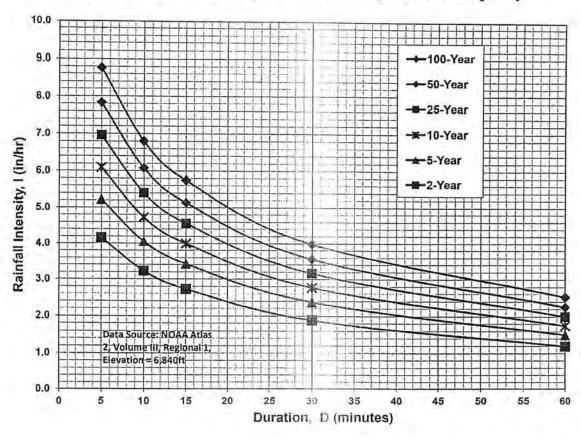

Figure 6-5. Colorado Springs Rainfall Intensity Duration Frequency

IDF Equations

$$I_{100} = -2.52 \ln(D) + 12.735$$

$$I_{50} = -2.25 \ln(D) + 11.375$$

$$I_{25} = -2.00 \ln(\mathbb{D}) + 10.111$$

$$I_{10} = -1.75 \ln(D) + 8.847$$

$$I_5 = -1.50 \text{ In}(D) + 7.583$$

$$I_2 = -1.19 \ln(D) + 6.035$$

Note: Values calculated by equations may not precisely duplicate values read from figure. $Q = \frac{0.463}{n} D^{8/3} S^{\frac{1}{2}}$

Subject: Double-Ring Infiltration Test Results

Project: Proposed Detention Pond Facility, All About Outdoor Storage, 16140 Old Denver Road,

Monument, Colorado

Project No: D19-2-189

Dear Kelly:

Vivid Engineering Group, Inc. (VIVID) has performed a double-ring infiltration test in general accordance with ASTM D3385 for the proposed detention pond facility located at 16140 Old Denver Road, Monument, Colorado.

Our services consisted of performing a double-ring infiltration test within the existing detention pond area that is planned for expansion. This effort also included advancing a geotechnical boring to check for lateral drainage during the infiltration test, and obtaining a subgrade sample for soil gradation analysis testing. This letter transmits our results.

FIELD INVESTIGATION

On April 9, 2019, a test pit was excavated within the existing detention pond area by All About Outdoor Storage personnel to a depth of approximately 1.5 feet below the ground surface. This is the approximate depth of the bottom of the proposed detention pond. The double-ring infiltration test was performed on April 9, 2019 within the excavated test location. Photographs depicting the test pit area are presented in Appendix C to letter.

At the completion of the double-ring infiltration test, a boring (boring B-1) was performed within the test pit for the purpose of checking for lateral drainage that may have occurred during the test. The boring was advanced to a depth of approximately 5.5 feet below the existing ground surface using a 3-inch diameter hand auger. A bulk sample was taken of the cuttings from the boring.

Appendix A to this letter includes a boring log describing the subsurface conditions encountered in the profile boring.

SUBGRADE CONDITIONS

From the ground surface down, the general subsurface profile encountered in the boring consisted of olive-yellow poorly graded sand. Neither bedrock nor groundwater were encountered in the profile boring. The boring log in Appendix A should be reviewed for a more detailed description of the subsurface conditions encountered.

LABORATORY TESTING

A sample of the subgrade materials were taken from the profile boring. Geotechnical laboratory testing was conducted and included soil gradation. The poorly graded sand materials were judged to be non-plastic and have only 4 percent fines (percent passing the No. 200 sieve). This type of clean sand material generally exhibits high permeability. Results of the geotechnical laboratory testing are presented in Appendix B.

DOUBLE-RING INFILTRATION TESTING

The average infiltration rate obtained at the test location was approximately **48.3 cm/hour**. Water was not observed moving laterally around the test location, based on the hand excavation of a shallow bore hole adjacent the double-ring infiltrometer test location.

The double-ring infiltration test results are indicative of the granular (sand) soil encountered on the site.

LIMITATIONS

This work was performed in a manner consistent with that level of care and skill ordinarily exercised by other members of VIVID's profession practicing in the same locality, under similar conditions and at the date the services are provided. Our conclusions and opinions are based on a limited number of observations and data. Data or conclusions presented herein apply to the specific test pit and test locations only. It is likely that subsurface conditions will vary somewhat beyond the locations investigated. VIVID makes no other representation, guarantee, or warranty, express or implied, regarding the services, communication (oral or written), report, opinion, or instrument of service provided.

CLOSING

We appreciate this opportunity to serve you, and we look forward to working with you again. Should you have any questions concerning this report, please contact Bill Barreire at 719.491.2292 or wbarreire@vivideg.com, or Benjamin Moore at 720.461.3692 or bmoore@vivideg.com.

Sincerely,

04-24-19

William (Bill) J. Barreire, PE Senior Geotechnical Engineer Benjamin Moore, EIT Staff Engineer

Ben Moore

Important Information About This Geotechnical Engineering Report

Important Information about This

Geotechnical-Engineering Report

Subsurface problems are a principal cause of construction delays, cost overruns, claims, and disputes.

While you cannot eliminate all such risks, you can manage them. The following information is provided to help.

The Geoprofessional Business Association (GBA) has prepared this advisory to help you – assumedly a client representative - interpret and apply this geotechnical-engineering report as effectively as possible. In that way, clients can benefit from a lowered exposure to the subsurface problems that, for decades, have been a principal cause of construction delays, cost overruns, claims, and disputes. If you have questions or want more information about any of the issues discussed below, contact your GBA-member geotechnical engineer. **Active involvement in the Geoprofessional Business** Association exposes geotechnical engineers to a wide array of risk-confrontation techniques that can be of genuine benefit for everyone involved with a construction project.

Geotechnical-Engineering Services Are Performed for Specific Purposes, Persons, and Projects

Geotechnical engineers structure their services to meet the specific needs of their clients. A geotechnical-engineering study conducted for a given civil engineer will not likely meet the needs of a civilworks constructor or even a different civil engineer. Because each geotechnical-engineering study is unique, each geotechnical-engineering report is unique, prepared solely for the client. Those who rely on a geotechnical-engineering report prepared for a different client can be seriously misled. No one except authorized client representatives should rely on this geotechnical-engineering report without first conferring with the geotechnical engineer who prepared it. And no one – not even you – should apply this report for any purpose or project except the one originally contemplated.

Read this Report in Full

Costly problems have occurred because those relying on a geotechnical-engineering report did not read it *in its entirety*. Do not rely on an executive summary. Do not read selected elements only. *Read this report in full*.

You Need to Inform Your Geotechnical Engineer about Change

Your geotechnical engineer considered unique, project-specific factors when designing the study behind this report and developing the confirmation-dependent recommendations the report conveys. A few typical factors include:

- the client's goals, objectives, budget, schedule, and risk-management preferences;
- the general nature of the structure involved, its size, configuration, and performance criteria;
- the structure's location and orientation on the site; and
- other planned or existing site improvements, such as retaining walls, access roads, parking lots, and underground utilities.

Typical changes that could erode the reliability of this report include those that affect:

- the site's size or shape;
- the function of the proposed structure, as when it's changed from a parking garage to an office building, or from a light-industrial plant to a refrigerated warehouse;
- the elevation, configuration, location, orientation, or weight of the proposed structure;
- the composition of the design team; or
- · project ownership.

As a general rule, *always* inform your geotechnical engineer of project changes – even minor ones – and request an assessment of their impact. The geotechnical engineer who prepared this report cannot accept responsibility or liability for problems that arise because the geotechnical engineer was not informed about developments the engineer otherwise would have considered.

This Report May Not Be Reliable

Do not rely on this report if your geotechnical engineer prepared it:

- for a different client;
- for a different project;
- for a different site (that may or may not include all or a portion of the original site); or
- before important events occurred at the site or adjacent to it; e.g., man-made events like construction or environmental remediation, or natural events like floods, droughts, earthquakes, or groundwater fluctuations.

Note, too, that it could be unwise to rely on a geotechnical-engineering report whose reliability may have been affected by the passage of time, because of factors like changed subsurface conditions; new or modified codes, standards, or regulations; or new techniques or tools. *If your geotechnical engineer has not indicated an "apply-by" date on the report, ask what it should be,* and, in general, *if you are the least bit uncertain* about the continued reliability of this report, contact your geotechnical engineer before applying it. A minor amount of additional testing or analysis – if any is required at all – could prevent major problems.

Most of the "Findings" Related in This Report Are Professional Opinions

Before construction begins, geotechnical engineers explore a site's subsurface through various sampling and testing procedures. Geotechnical engineers can observe actual subsurface conditions only at those specific locations where sampling and testing were performed. The data derived from that sampling and testing were reviewed by your geotechnical engineer, who then applied professional judgment to form opinions about subsurface conditions throughout the site. Actual sitewide-subsurface conditions may differ – maybe significantly – from those indicated in this report. Confront that risk by retaining your geotechnical engineer to serve on the design team from project start to project finish, so the individual can provide informed guidance quickly, whenever needed.

This Report's Recommendations Are Confirmation-Dependent

The recommendations included in this report – including any options or alternatives – are confirmation-dependent. In other words, they are not final, because the geotechnical engineer who developed them relied heavily on judgment and opinion to do so. Your geotechnical engineer can finalize the recommendations only after observing actual subsurface conditions revealed during construction. If through observation your geotechnical engineer confirms that the conditions assumed to exist actually do exist, the recommendations can be relied upon, assuming no other changes have occurred. The geotechnical engineer who prepared this report cannot assume responsibility or liability for confirmation-dependent recommendations if you fail to retain that engineer to perform construction observation.

This Report Could Be Misinterpreted

Other design professionals' misinterpretation of geotechnicalengineering reports has resulted in costly problems. Confront that risk by having your geotechnical engineer serve as a full-time member of the design team, to:

- confer with other design-team members,
- help develop specifications,
- review pertinent elements of other design professionals' plans and specifications, and
- be on hand quickly whenever geotechnical-engineering guidance is needed.

You should also confront the risk of constructors misinterpreting this report. Do so by retaining your geotechnical engineer to participate in prebid and preconstruction conferences and to perform construction observation.

Give Constructors a Complete Report and Guidance

Some owners and design professionals mistakenly believe they can shift unanticipated-subsurface-conditions liability to constructors by limiting the information they provide for bid preparation. To help prevent the costly, contentious problems this practice has caused, include the complete geotechnical-engineering report, along with any attachments or appendices, with your contract documents, but be certain to note conspicuously that you've included the material for informational purposes only. To avoid misunderstanding, you may also want to note that "informational purposes" means constructors have no right to rely on the interpretations, opinions, conclusions, or recommendations in the report, but they may rely on the factual data relative to the specific times, locations, and depths/elevations referenced. Be certain that constructors know they may learn about specific project requirements, including options selected from the report, only from the design drawings and specifications. Remind constructors that they may

perform their own studies if they want to, and *be sure to allow enough time* to permit them to do so. Only then might you be in a position to give constructors the information available to you, while requiring them to at least share some of the financial responsibilities stemming from unanticipated conditions. Conducting prebid and preconstruction conferences can also be valuable in this respect.

Read Responsibility Provisions Closely

Some client representatives, design professionals, and constructors do not realize that geotechnical engineering is far less exact than other engineering disciplines. That lack of understanding has nurtured unrealistic expectations that have resulted in disappointments, delays, cost overruns, claims, and disputes. To confront that risk, geotechnical engineers commonly include explanatory provisions in their reports. Sometimes labeled "limitations," many of these provisions indicate where geotechnical engineers' responsibilities begin and end, to help others recognize their own responsibilities and risks. *Read these provisions closely*. Ask questions. Your geotechnical engineer should respond fully and frankly.

Geoenvironmental Concerns Are Not Covered

The personnel, equipment, and techniques used to perform an environmental study – e.g., a "phase-one" or "phase-two" environmental site assessment – differ significantly from those used to perform a geotechnical-engineering study. For that reason, a geotechnical-engineering report does not usually relate any environmental findings, conclusions, or recommendations; e.g., about the likelihood of encountering underground storage tanks or regulated contaminants. Unanticipated subsurface environmental problems have led to project failures. If you have not yet obtained your own environmental information, ask your geotechnical consultant for risk-management guidance. As a general rule, do not rely on an environmental report prepared for a different client, site, or project, or that is more than six months old.

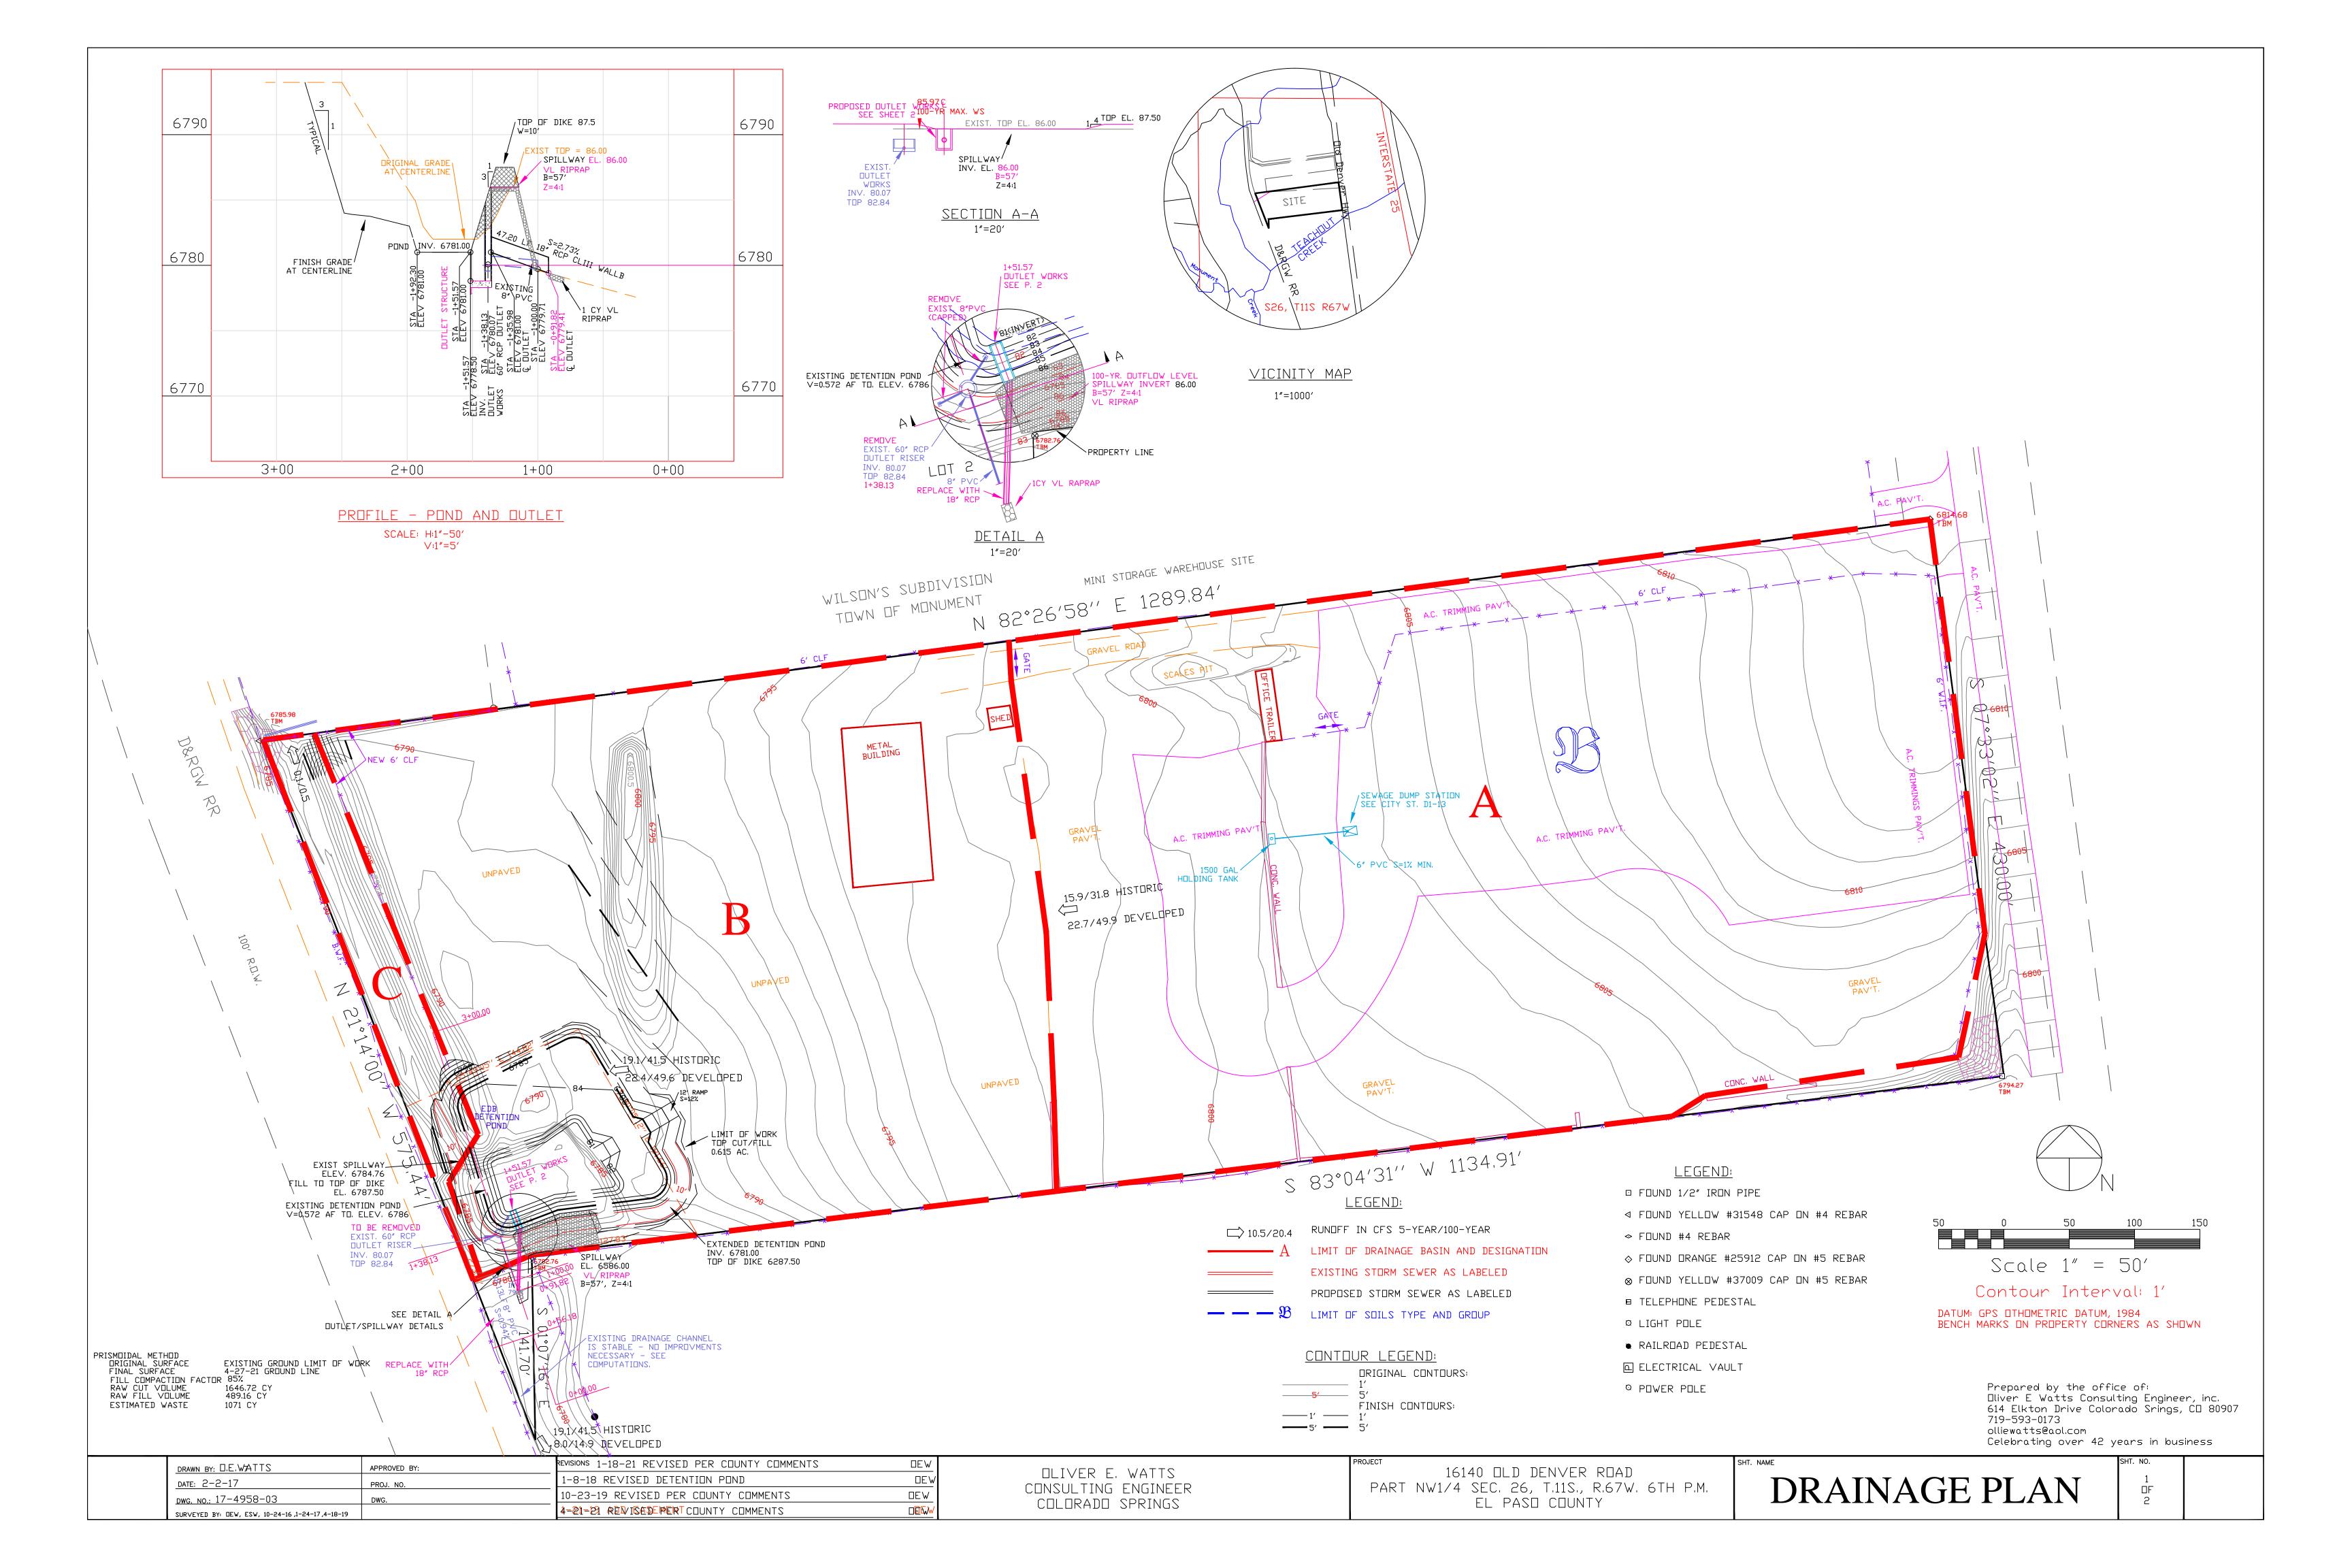

Obtain Professional Assistance to Deal with Moisture Infiltration and Mold

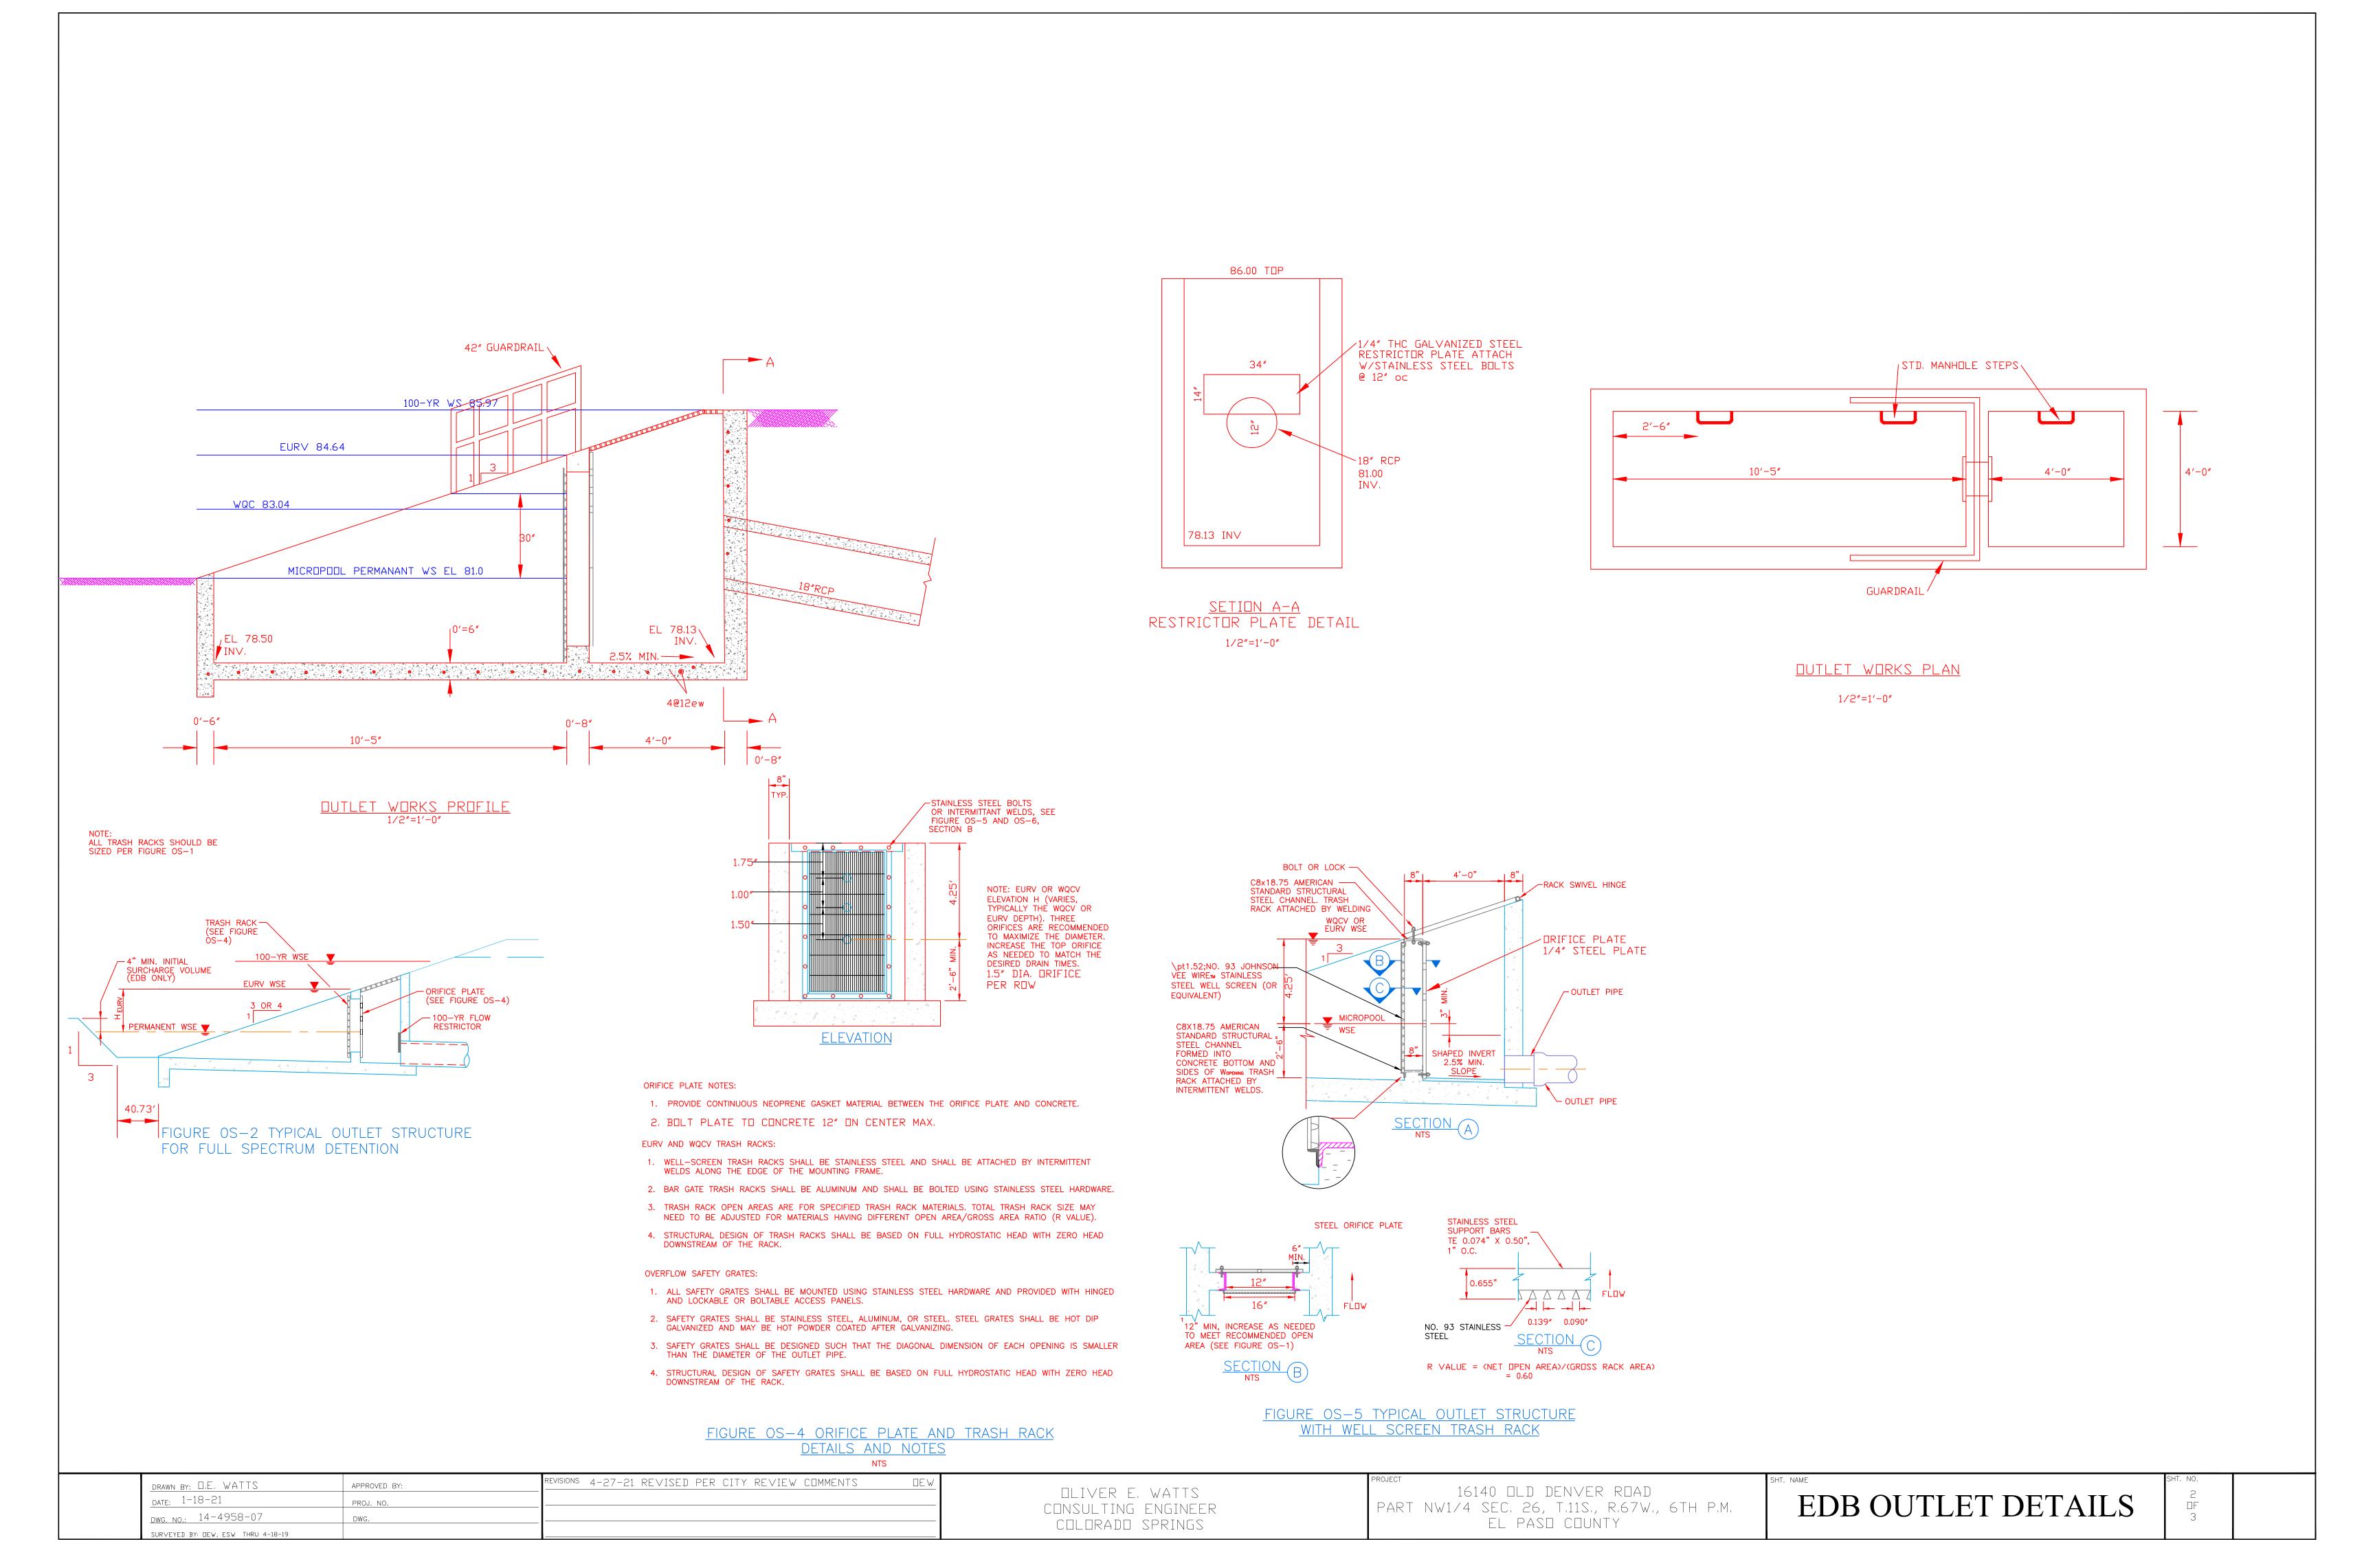

While your geotechnical engineer may have addressed groundwater, water infiltration, or similar issues in this report, none of the engineer's services were designed, conducted, or intended to prevent uncontrolled migration of moisture – including water vapor – from the soil through building slabs and walls and into the building interior, where it can cause mold growth and material-performance deficiencies. Accordingly, proper implementation of the geotechnical engineer's recommendations will not of itself be sufficient to prevent moisture infiltration. Confront the risk of moisture infiltration by including building-envelope or mold specialists on the design team. Geotechnical engineers are not building-envelope or mold specialists.
